Re: *Site Investigation Report*
Former Truk-Away Landfill
Warwick Industrial Drive
Warwick, Rhode Island

Dear Mr. Walusiak:

On behalf of the Truk-Away Landfill Joint Defense Group (Group), GZA GeoEnvironmental, Inc. (GZA) is pleased to provide this *Site Investigation Report* (SIR) for the Former Truk-Away Landfill (Site). This report has been prepared to address the applicable requirements of Rule 1.8 of the RIDEM Rules and Regulations for the Investigation and Remediation of Hazardous Material Releases, including the evaluation of remedial alternatives. This report is presented subject to the Limitations presented in Appendix A.

We trust this submittal satisfies your present needs. If you need any additional information, please feel free to contact Richard Carlone at 401-421-4140 or via email at richard.carlone@gza.com.

Very truly yours,

GZA GEOENVIRONMENTAL, INC.

Richard A. Carlone, P.E.
Senior Project Manager

1.0 INTRODUCTION

1.1 PROJECT AUTHORIZATION

GZA GeoEnvironmental, Inc. (GZA) prepared this *Site Investigation Report* (SIR) on behalf of Truk-Away Landfill Joint Defense Group (Group) for the Former Truk-Away Landfill located off of Warwick Industrial Drive in Warwick, Rhode Island (Site). Authorization to proceed on this project was granted in accordance with GZA's signed proposal dated May 15, 2019. This report may be subject to modification if additional information is developed subsequently by GZA or any other party. This SIR is subject to the limitations provided in **Appendix A**.

The landfill is subject to two of the Rhode Island Department of Environmental Management's (RIDEM's) regulatory programs; the Solid Waste Program and the Site Remediation Program. This report was prepared to address the applicable requirements established in Section 1.8 of RIDEM's Rules and Regulation for the Investigation and Remediation of Hazardous Materials Releases dated January 2019 (Remediation Regulations); the Solid Waste Program's Solid Waste Regulations No. 2, dated March 2018; and the Closure Policy for Inactive or Abandoned Solid Waste Landfills, dated March 1, 2007.

An SIR Checklist is attached as **Appendix B**. The checklist references previous reports for the Site, as applicable, see Section 1.4, as well as the required information provided in this SIR.

A public notice was distributed on August 8, 2019 announcing that a Site Investigation would commence, as required in RIDEM's Remediation Regulations. The public notice was sent to owners of abutting properties and tenants, local government officials and easement holders.

1.2 PROJECT BACKGROUND

RIDEM reports that the Former Truk-Away Landfill covers approximately 36 acres of a 54-acre property located off of Industrial Drive in Warwick, Rhode Island; the location of the Site is shown on **Figure 1**. It was operated as a solid waste landfill between 1970 and 1978. RIDEM files indicate that the landfill reportedly accepted household/municipal, industrial, institutional, commercial and hazardous waste. The Rhode Island Department of Transportation (RIDOT) took ownership of the property in 1977. The Rhode Island Airport Corporation (RIAC) currently owns the Site and the Rhode Island Department of Administration (RIDOA) is the lead agency implementing the investigation and closure of the former landfill.

Several previous investigations have been conducted at the Site and have identified the following environmental concerns:

- Volatile organic compounds (VOC) at concentrations in groundwater above RIDEM's Method 1 GB Groundwater Objectives;
- The presence of light non-aqueous phase liquid (LNAPL), primarily in one onsite groundwater monitoring well (MW-3), which also contained elevated levels of polychlorinated biphenyls (PCBs) in the LNAPL; and
- Elevated levels of methane and VOCs in soil gas.

1.3 PROJECT OBJECTIVES

Based on the environmental concerns identified above, GZA conducted a Site Investigation in accordance with the RIDEM-approved August 16, 2019 Site Investigation Work Plan (SIWP). The following objectives were identified in the SIWP:

- Complete a Site Investigation to address the applicable sections of the RIDEM Remediation and Solid Waste Regulations, as referenced above;
- Evaluate the landfill's potential impacts to human health and the environment;

- Further evaluate the limits of waste;
- Evaluate the extent of any adjacent wetland areas;
- Evaluate the thickness of the existing landfill cover materials and cover soils uniformity at the required minimum thickness of 2-feet across the former landfill;
- Evaluate whether the existing cover materials contain regulated contaminants at concentrations above the Method 1 Residential Direct Exposure Criteria (RDEC);
- Evaluate the current landfill topography to support future landfill closure and cap design;
- Install a groundwater monitoring well network, up-gradient and down-gradient of the landfill, to document current groundwater quality conditions and groundwater/contaminant migration patterns;
- Install a landfill gas monitoring network to evaluate off-site subsurface landfill gas migration;
- Collect sediment and surface water samples to evaluate the extent and source of impacts;
- Evaluate LNAPL/PCB impacts in the vicinity of existing monitoring well MW-3;
- Evaluate the possible presence of a 15,000-gallon underground storage tank (UST) on-Site;
- Perform a streamlined Screening Level Ecological Risk Assessment (SCLERA) for surface water and sediment;
- Evaluate and recommend appropriate remedial measures which account for the State's long-term property use goals and meet the remedial objects associated with the RIDEM Remediation and Solid Waste Regulations; and
- Develop this *Site Investigation Report* that identifies three feasible remedial alternatives (including the no-action alternative) and includes a recommended remedial alternative for the project.

1.4 FILE REVIEW

GZA has reviewed files provided by RIDEM. Pertinent documents reviewed and referenced throughout this report are:

- *Final Site Inspection Prioritization* dated December 1993 by Camp Dresser & McKee, Inc. (CDM);
- *Mercury contamination at the former Truk-Away Landfill* dated May 1999 by RIDEM;
- *Limited Site Investigation Work Plan* dated August 2000 by CDM;
- *Preliminary Subsurface Investigation and Geotechnical Feasibility Study* dated January 2001 by CDM;
- *Limited Environmental Site Investigation Report* dated March 2001 by CDM;
- *Preliminary Cost Estimate Report* dated January 2002 by CDM;
- *Truk-Away Landfill* dated February 2005 by Lincoln Environmental, Inc. (Lincoln);
- *Site Investigation Report* dated September 2008 by EA Engineering, Science, and Technology, Inc. (EA);
- Data from the Buckeye Brook Total Maximum Daily Load (TMDL) evaluation provided by RIDEM;
- RIDEM Environmental Resources Map; and
- City of Warwick Web GIS Maps and Online Property Information.

2.0 BACKGROUND

The following background information was developed from the various documents listed in Section 1.4, attached as **Appendix C**. Please refer to these reports for additional detailed information.

2.1 SITE LOCATION, DESCRIPTION AND USE

The former Truk-Away Landfill is located off of Warwick Industrial Drive, in Warwick, Rhode Island. A Locus Plan is provided as **Figure 1**. The property is owned by Rhode Island Airport Corporation (RIAC). Approximately 36 acres of the 54-acre property is occupied by an unlined solid waste landfill.

The landfill is currently untended vacant land, which is heavily vegetated with tall grass, shrubs, trees and wetlands. There are currently no buildings present on the property. It is bordered to the north by a runway for T.F. Green Airport, to the north, south and east by wetlands including Buckeye Brook, to the south by residential housing and to the west by industrial properties.

An Exploration Plan is provided as **Figure 2**, which also depicts key Site features, including the delineated landfill footprint (inferred limits of waste), and existing topography. The Site is secured with a chain-link fence, although evidence of trespassing was visible during the investigation.

2.2 SITE HISTORY

The Site was operated as a privately-owned solid waste landfill beginning in 1970, under the name of Warwick Sanitary Landfill. In 1976 the company changed its name to Truk-Away of Rhode Island, Inc. The landfill reportedly accepted household/municipal, industrial, institutional, commercial and hazardous waste. RIDOT assumed ownership of the property in 1977 and landfill operations ceased in 1978. The RIAC currently owns the Site and the RIDOA is the lead agency implementing the investigation and closure of the landfill.

3.0 ENVIRONMENTAL SETTING

The following subsections provide information regarding the general physiographic and hydrogeologic conditions in the area of the Site.

3.1 TOPOGRAPHY, DRAINAGE, SOIL TYPE

Based on a review of the 2018 U.S. Geological Survey topographic map and online GIS mapping, the Site is at an elevation of ±60 feet above mean sea level (MSL). The Site has an approximate 30-foot elevation change from the highest area in the middle of former landfill, to the lowest areas in the wetlands surrounding the north, east and south of the landfill footprint. The regional topographic gradient near the Site slopes downward to the east towards the adjacent Buckeye Brook.

According to the Bedrock Geology Map of the East Greenwich Quadrangle, Rhode Island, dated 1952, the underlying bedrock is Rhode Island Formation (Esmond-Dedham Subterrane) and is described as greenish, gray, dark-gray, to black greywacke, conglomerate, sandstone, shale, and meta-anthracite. Based on review of available mapping, bedrock appears to be located approximately 50 feet below ground surface (bgs). According to the Surficial Geology Map of the East Greenwich Quadrangle, dated 1955, the surficial soils in the vicinity of the Site are comprised of artificial fill underlain by glacial outwash plains. Outwash plains consist of sorted sand, stratified silts, and local deposits of gravel, and can be highly permeable.

The Unites States Natural Resources Conservation Service's Web Soil Survey classifies surficial Site soils as "Dumps" (human transported material) and "Scarboro mucky fine sandy loam" (0 to 3 percent slopes that are very poorly drained).

3.2 GROUNDWATER

Groundwater at the Site is classified as GB by RIDEM. This designation applies to groundwater resources which may not be suitable for human consumption without treatment due to known or presumed degradation. The Site is not located within an area designated as a Groundwater Reservoir. The Site is located approximately 0.9 miles west (upgradient) of an area with a GA Groundwater Classification.

Based on local topography, the inferred direction of groundwater flow is to the east toward the Buckeye Brook. However, the localized direction of groundwater flow near the Site might vary because of underground utilities, subsurface preferential pathways, variations in weather or heterogeneous geological and/or anthropogenic conditions.

According to overlay maps maintained by the RIDEM's Office of Water Resources, the Site is located approximately 3.8 miles east of a non-community wellhead protection area and over 5 miles away from any community wellhead protection areas.

The area surrounding the Site is supplied with public water. We did not verify if potable wells are present on adjacent properties.

3.3 SURFACE WATER

An unnamed brook borders the northern perimeter of the Site and flows into the Buckeye Brook. The Buckeye Brook has been classified as B water by RIDEM which stipulates that these waters are designated for fish and wildlife habitat and primary and secondary contact recreational activities. They shall be suitable for compatible industrial processes and cooling, hydropower, aquaculture uses, navigation, and irrigation and other agricultural uses. These waters shall have good aesthetic value with the caveat that primary contact recreational activities may be impacted due to pathogens from approved wastewater discharges.

The unnamed brook and Buckeye Brook are currently listed by the RIDEM Office of Water Resources on the State of Rhode Island 2016 303(d) List of Impaired Waters, dated March 2018. The 2016 303(d) list identifies water bodies within the state, which may not currently meet Rhode Island Water Quality Standards and for which a Total Maximum Daily Load (TMDL) may be needed. TMDLs are water quality restoration plans that identify water quality goals, necessary pollutant reductions, sources, and implementation plans to achieve the required reductions. RIDEM identifies the unnamed brook and segment of the Buckeye Brook adjacent to the Site as Water Body ID RI0007024R-01 and lists the impairments as benthic-macroinvertebrate bioassessments, cadmium, copper, enterococcus, fecal coliform, iron and dissolved oxygen.

A bacteria TMDL was completed for Buckeye Brook in December 2008 and bacteria impairments were noted in the watershed, as described above. Between 2008 and 2011, RIDEM performed a water quality TMDL evaluation on Buckeye Brook. Study locations TA01 and AP01 were located downgradient from the landfill Site. TA01 sample concentrations taken during dry and wet weather exceeded RIDEM's Freshwater Aquatic Chronic Criteria for cadmium and iron. The AP01 dry weather sample had an elevated total organic carbon (TOC) result, as well as an iron concentration that exceeded RIDEM's Freshwater Aquatic Chronic Criteria. A sampling location map and a summary of the data is included in **Appendix C**.

A review of the *Environmental Resource Map* prepared by RIDEM (http://www.dem.ri.gov/maps/) shows that the Site is located in the Upper Narragansett Bay Watershed. Stormwater at the Site is primarily managed naturally and either flows downgradient from west to east directly into the Buckeye Brook or is sequestered by infiltration through the soils/waste.

Based on a review of Federal Emergency Management Agency (FEMA) Map #44003C0133H dated September 18, 2013, the majority of the Site is located within Zone X. The Zone X designation is for areas with a 0.2% annual chance of flood; areas of 1% annual chance of flood with average depths of less than 1 foot or with drainage areas less than 1-square mile; and areas protected by levees from 1% annual chance of flood. The brook and wetland areas along the north, east and south of the Site are designated by FEMA as an "A, Without Base Flood Elevation (BFE)" zone.

3.4 ENVIRONMENTALLY SENSITIVE AREA

According to the overlay maps maintained by RIDEM's Office of Water Resources, the area along the northeast perimeter of the Site is located within a Natural Heritage Area.

4.0 SITE HISTORY

The landfill is owned by the RIAC and the RIDOA is the lead agency implementing the investigation and closure of the landfill. The Site contains a former unlined municipal solid waste (MSW) landfill that operated from 1970 until 1978. While in operation, the landfill reportedly accepted MSW, household, industrial, institutional, commercial and hazardous waste. The facility began

operations in the elevated northwest section of the property, and then began dumping in the "swampy areas" without first placing any clean material as required by the Rhode Island Department of Health (RIDOH), Division of Solid Waste Management.

During its operation, the landfill was the subject of several complaints including a roach problem, odors due to decaying organic matter and several daily cover and wind-blown refuse control violations. Leachate outbreaks have been historically observed on the eastern, southeastern and southern slopes of the landfill. Prior to the Site's use as a landfill, the property was utilized as a sand and gravel pit. Note that leachate seeps were not observed during GZA's investigation.

4.1 REGULATORY HISTORY

The Site is included on RIDEM's State Solid Waste Facilities/Landfill list and "State Sites" inventory and is also inventoried on the U.S. Environmental Protection Agency's (USEPA's) Comprehensive Environmental Response, Compensation, and Liability Information System (CERCLIS) list. The Site has an EPA ID of RID987493822 and a State Site ID of SR-35-1576. The CERCLIS list indicates that the State is taking primary oversight responsibility for investigation. The Site is not on the National Priorities List (NPL – Superfund List).

This site investigation has been performed in accordance with the *Closure Policy for Inactive or Abandoned Solid Waste Landfills* (RIDEM March 2001), Section 1.8 of the *Remediation Regulation* and the *Solid Waste Regulations No.2*. In this regard, the goal is to effectuate a remedial action in accordance with applicable RIDEM policies and regulations that results in the issuance of a *Letter of Compliance* from the RIDEM, a *Letter of No Further Action* from the USEPA, and the archival of the Site from CERCLIS.

4.2 REVIEW OF PREVIOUS REPORTS, HISTORICAL DATA AND SITE ASSESSMENTS

The USEPA directed a Site Inspection Prioritization (SIP) in 1993, by CDM. The RIAC also directed several environmental assessments at the Site in the 2000s. These included a Preliminary Subsurface Investigation and Geotech Feasibility Study in January 2001, a Limited Environmental SIR in March 2001 and a Preliminary Cost Estimate Report in January 2002 conducted by CDM. Lincoln conducted a Site Investigation in February 2005 for RIDEM, and EA conducted a Site Investigation in September 2008 for RIDOA. These investigations consisted of soil sampling, sediment sampling, leachate sampling, groundwater sampling, soil gas screening and wetland delineation. Sections 4.2.1 through 4.2.4 discuss the findings of these prior investigations.

4.2.1 CDM Site Investigations

In 1993, CDM conducted sediment and soil sampling, which indicated the presence of VOCs, semi volatile organic compounds (SVOCs), PCBs and Metals. In 2000 CDM further investigated the Site to assess its suitability for redevelopment and advanced 23 test pits around the perimeter of the Site to determine the lateral extent of landfill material. Landfill material extended beyond the southern and western Site boundaries and consisted of plastic, glass, wood, rubber, cloth, and brick. Eight soil borings were performed, with six monitoring wells installed (MW-1, MW-3, MW-5, MW-6, MW-7 and MW-8). A maximum waste material thickness of 40 feet was noted at MW-3 in the central portion of the Site. The soil sample with the highest PID reading from each boring was submitted for VOCs, SVOCs, total petroleum hydrocarbon (TPH), PCBs, TOC, metals, and pesticides analyses. All compounds were below the applicable RIDEM GB Leachability Criteria and only arsenic was detected at levels exceeding the RIDEM Industrial/Commercial Direct Exposure Criteria (I/C-DEC). Six wetland areas were also delineated across the Site.

In November 2000, groundwater samples were collected from the six newly installed wells and analyzed for Hazardous Substance List (HSL) VOCs, SVOCs, PCBs, pesticides, metals, nitrate nitrogen, alkalinity, chemical oxygen demand (COD), chlorides, total dissolved solids (TDS), total cyanide and sulfate. An approximately 2-foot thick layer of LNAPL was observed in MW-3 and a <1/4-inch thick layer of LNAPL was observed in MW-5. Two VOCs (toluene and ethylbenzene) were detected at levels exceeding the RIDEM GB Groundwater Objective in MW-3 and MW-8.

CDM also installed 16 soil vapor probes around the landfill perimeter and on the top of the landfill in November 2000. Landfill gas, particularly elevated levels of methane, were noted in 8 out of the 16 probe locations.

4.2.2 Lincoln Site Investigation

Lincoln conducted a groundwater sampling event in December 2004. During this event, 1.08 ft of LNAPL was observed in MW-3, but there was no evidence of the previously observed LNAPL at MW-5. Groundwater samples were collected from each of the six on-Site wells (MW-1, MW-3, MW-5, MW-6, MW-7 and MW-8) and analyzed for VOCs, SVOCs and PCBs. A LNAPL sample was also collected from MW-3 and submitted for TPH fingerprinting and PCB analysis. The LNAPL was shown to be a mix of gasoline and motor oil and results also indicated the presence of two PCBs (Aroclor 1016 at 68 mg/kg and 1260 at 48 mg/kg). This exceeded the USEPA Toxic Substances Control Act's (TSCA's) 50 parts per million (ppm) limit. No PCBs were detected in groundwater, and the concentrations of detected VOCs and SVOCs were below the applicable RIDEM criteria.

4.2.3 EA Site Investigation

Between March and May 2008 five soil borings were advanced in the vicinity of MW-3 and two groundwater monitoring wells (MW-EA1 and MW-EA2) were installed. Nine soil vapor points were also installed in the vicinity of the previously encountered pocket of landfill gas and surveyed. Results of the soil gas survey indicated that the levels of soil gas present exceeded the Lower Explosive Limit (LEL) for methane at all but one location in the vicinity of MW-3.

Groundwater samples were collected from seven of the on-Site wells (MW-1, MW-5, MW-6, MW-7, MW-8, MW-EA1 and MW-EA2) in June 2008 and analyzed for VOCs. All concentrations of detected VOCs were below the RIDEM GB Groundwater Objectives. A LNAPL sample was also collected from MW-3 and submitted for analysis of VOCs, SVOCs, PCBs and pesticides. Only one PCB (Aroclor 1260) was detected in the LNAPL sample, at a concentration below the 50 ppm TSCA Limit.

5.0 SITE INVESTIGATION

In accordance with the RIDEM-approved August 16, 2019 SIWP, GZA conducted a Site Investigation to achieve the objectives listed in Section 1.3. The Site Investigation was completed between September 2019 and March 2020, and consisted of the following field activities:

- A topographic survey using Aerial Digital Photogrammetry;
- Flagging of the wetlands adjacent to the landfill;
- A geophysical survey and test pits to evaluate the possible presence of USTs on-Site;
- Test pits to delineate the edge of waste and evaluate cover soil thickness;
- Eight Geoprobe® direct push explorations outside of the landfill footprint, with the installation of a groundwater monitoring well in each;
- Four Geoprobe® direct push/auger explorations around MW-3 to further delineate LNAPL/PCB impacts;
- The collection of 19 groundwater samples (12 newly installed wells and 7 existing wells) for VOCs, SVOCs, TPH, Pesticides, PCBs and 15 Solid Waste Metals/Mercury analysis;
- The installation of 13 soil gas probes along the perimeter of the landfill using a Geoprobe® rig and hand driven methods;
- Two rounds of landfill gas (LFG) field measurements;
- The collection 11 sediment samples using the Vibecore-Mini3 sediment sampler for VOCs, SVOCs, TPH, Pesticides, PCBs and 15 Solid Waste Metals/Mercury;
- The collection of 11 surface water samples for VOCs, SVOCs, TPH, Pesticides, PCBs, 15 dissolved Solid Waste Metals/Mercury/Iron and TOC; and
- A complete exploration location survey.

The Site investigation was conducted in accordance with the SIWP. The following deviations were made from the SIWP as noted in GZA's December 5, 2019 email to the Department:

- Soil gas probes were installed in the locations shown in the SIWP generally using hand driven stainless-steel points, rather than as drill rig installed PVC probes. This was necessary due to access limitations (trees, wet areas, etc.). The probes were driven to about 5 feet below ground surface with the bottom six inches screened; and
- The downgradient monitoring wells were installed as close to the locations shown in the SIWP as practical, based on accessibly (standing water, etc.), with the recognition that some were installed within the waste footprint.

5.1 TOPOGRAPHIC SURVEY

WSP USA, INC., under contract to GZA, conducted a topographic survey of the Site on November 22, 2019. The topographic survey was conducted using Aerial Digital Photogrammetry via an airplane with a contour interval of one (1) foot to support future landfill closure/cap design. Survey ground control points were established to align the topographic survey to the Rhode Island State Plan Coordinate System in the North American Datum NAVD 83 and NAVD 88. These points were established using a Leica Zeno 20 (L1/L2) Collector with an AS-10 antenna using real-time kinematic (RTK) correction with an accuracy of 1.0 cm horizontal and 2.0 cm vertical. Existing State Light Detection and Ranging (LIDAR) survey data was also integrated into the plan to show property features and the topography of relevant adjacent areas.

The results of this survey are shown on **Figure 2**.

5.2 WETLANDS FLAGGING

A GZA biologist flagged on-Site wetlands on October 16 and October 22, 2019. Jurisdictional wetlands are present at the southern, eastern and northern landfill toe-of-slope, and are shown on **Figure 2**.

GZA identified three wetland areas on the Site with flagging as follows:

- A1 to A105 (Pink and black striped flagging on the south, east and north of Site);
- B1 to B25 (Pink and black striped flagging on the northwest portion of Site); and
- TOB-A1 to TOB-A7 and TOB1 to TOB27 (Pink flagging on the banks of a perennial stream);

The wetland flag locations and associated perimeter wetlands are shown on Figure 2.

5.3 TANK INVESTIGATION

A 15,000-gallon UST was reportedly located near the former on-Site building. A ground penetrating radar (GPR) survey of the area where the tank was reportedly located was completed on October 2, 2019 by Thielsch Engineering, with oversight provided by GZA. Five anomalies (indicating a potential buried object/structure) were noted and test pits were completed by Hoffman Environmental Services of North Kingstown, Rhode Island in the area of each anomaly on December 3, 2019. No USTs were located; the anomalies from the GPR survey included a scale (presumably used for weighing incoming materials as part of the former landfilling operations), a former dry well/cesspool and buried concrete/metal debris.

Location	Anomaly Found
GPR-1	Former scale
GPR-2	Dry well
GPR-4	Rotted out drum
GPR-5	Sheet metal
GPR-9	Scrap metal

5.4 TEST PIT EXPLORATIONS

Between December 2 and 4, 2019 GZA observed the completion of 11 test pits (TP-1 to TP-11) by Hoffman Environmental Services of North Kingstown, Rhode Island using a CAT 303.5E2 Mini Excavator with a 10 ft reach. See **Figure 2** for test pit locations.

A GZA field engineer was present during the exploration activities to coordinate and document the program, classify soils, prepare test pit logs, field-screen soil samples and collect/prepare samples for laboratory testing. Samples were characterized in the field and test pit logs maintained for each test pit. Copies of the test pit logs are provided in **Appendix D**.

5.4.1 Edge of Waste Delineation

Four test pits (TP-3, TP-5, TP-8 and TP-11) were excavated around the perimeter of the southern and northeastern suspected waste footprint, to supplement the previous edge of waste delineation in areas where data gaps existed. Waste was encountered in all four test pits, at depths ranging from 0-3 ft bgs. Below the waste layer, soils consisted of dark gray/brown sand with varying degrees of gravel and silt.

Generally, the observed edge of waste is consistent with the previous delineation and the updated delineated edge of waste is shown on **Figure 2**. As shown on **Figure 2**, approximately 3.5 acres of the landfill footprint appears to be within flagged wetland areas, most of which is located on the northeastern side of the landfill.

5.4.2 Cover Soil Evaluation

Seven test pits (TP-1, TP-2, TP-4, TP-6, TP-7, TP-9 and TP-10) were excavated across the top of the landfill to evaluate soil cover thickness. In areas where existing cover soil was at least two feet deep, a surficial soil sample was collected and placed into laboratory provided bottles, preserved as appropriate, packed in ice chests and transported under chain-of-custody protocol to ESS Laboratory in Cranston, Rhode Island. A total of three samples (TP-4, TP-7 and TP-9) and two trip blanks were analyzed for one or all of the following parameters:

- VOCs via EPA Method 8260B;
- SVOCs via EPA Method 8270C; and
- 15 Solid Waste Metals via EPA Method 6010B.

In the remaining locations (TP-1, TP-2, TP-3, TP-5, TP-6, TP-8 and TP-11) waste was encountered between 0-2 ft bgs, thus no soil samples were collected.

Note that there were many areas of ponded/perched water within the landfill footprint and areas of soft cover material. Certain areas also contained stockpiles that reportedly consist of street sweepings. These issues will need to be addressed as part of Site capping/closure.

5.5 SOIL BORINGS AND MONITORING WELL INSTALLATIONS

Between December 2, 2019 and January 1, 2020, GZA observed the completion of 12 borings (MW-101 to MW-105, MW-106S/MW-106D, MW-107, and MW-109 to MW-112) by Hoffman Environmental Services using a direct-push/hollow stem auger Geoprobe® rig. Borings were advanced to depths of between 10 and 30 ft bgs.

All 12 locations were completed as groundwater monitoring wells consisting of a 0.010-inch factory slotted nominal 2-inch inside diameter, flush joint, schedule 40 PVC well screen with solid PVC riser, except for MW-110 which was constructed as a 1-inch inside diameter PVC well. The annular space between the well screen and the borehole was filled with a filter sand pack. The sand pack was carried to a depth of 2-feet above the slotted section of the well screen where a 2-foot thick bentonite seal was placed. Any

non-contaminated drill cuttings (based on PID field screening results, described below) were then placed above the bentonite seal to ground surface.

A GZA field engineer was present during the exploration activities to coordinate and document the program, classify soils, prepare boring logs and field-screen soil samples. Samples were characterized in the field and boring logs maintained for each borehole. Copies of boring logs are provided in **Appendix D**.

Soil samples were collected continuously by pneumatically advancing a 5-foot, 2-inch ID steel split-spoon equipped with a dedicated acetate lining. Samples were recovered from a depth of 0 to 5, 5 to 10, 10 to 15, 15 to 20, 20 to 25, 25 to 30 and 30 to 35 feet bgs or refusal, whichever came first. Soil samples recovered for screening were transferred to clean, unpreserved 8-ounce glass jars using a stainless-steel trowel. A new acetate liner was employed for each sample.

5.5.1 Observed Subsurface Conditions

Soil samples recovered during the boring program were observed to generally consist of fine to coarse sand with varying degrees of gravel and silt in all borings. Peat was observed in MW-103 and MW-104 between 4 and 20 ft bgs. Waste was observed in MW-102, MW-105, MW-106S, MW-107, MW-109, MW-111 and MW-112 between 0 and 30 ft bgs. Soil samples were not collected from two borings (MW-106D and MW-110). Refer to the boring logs in **Appendix D** for additional subsurface information. Observed waste consisted included wood, plastic, metal, glass and brick.

5.5.2 Soil Sample Field Screening

Soil samples recovered during drilling activities were field-screened for total volatile organic compounds (TVOC) using a MiniRae model 3000 Photoionization Detector (PID) equipped with a 10.6 eV lamp and calibrated with a mixture of isobutylene in air. TVOC screening results are provided on the boring logs attached as **Appendix D**.

The TVOC readings were generally low, i.e. below 5 ppm, except in MW-109 between approximately 3 and 5 feet bgs, where an elevated PID screening result of 6.2 ppm was observed.

5.6 GROUNDWATER SAMPLING

Between January 7 and February 14, 2020, groundwater samples were collected from the 12 newly installed wells (MW-101 to MW-105, MW-106S, MW-106D, MW-107 and MW-109 to MW-112) and the seven previously installed wells which could be field located (MW-1, MW-3, MW-5, MW-6, MW-7, MW-8 and MW-EA-01). The groundwater sampling program was executed in accordance with the Work Plan.

Groundwater samples were collected in general accordance with EPA's September 19, 2017 *Low Stress (low flow) Purging and Sampling Procedure* (low flow SOP). As part of that sampling methodology, well stabilization was evaluated through the measurement of specific water quality parameters recorded during the purging process. A variable speed peristaltic pump was utilized to control the rate of purging and limit the drawdown caused by this operation. To avoid cross contamination, dedicated 3/8-inch-outer-diameter (OD) polyethylene tubing, installed in each of the existing wells, was utilized as the intake and discharge tubing for the pumps. Pharmaceutical grade tubing was employed as the pump head tubing and connected to the intake and discharge tubing by clamps sufficient to prevent the introduction of air into the sample.

Prior to sampling, each well was gauged for light and dense non-aqueous phase liquids (LNAPL and DNAPL); no LNAPL or DNAPL was observed in any of the new wells. An approximately 0.81-foot thick layer of LNAPL was present in MW-3 and an approximately 0.70-feet thick layer of LNAPL was present in MW-EA-01, where it has historically been observed.

During the sampling, field readings were recorded for pH, temperature, specific conductance, dissolved oxygen, oxygen reduction potential (ORP) and turbidity using a YSI Pro Series multi-meter with a flow-through cell. Field equipment used to

perform the testing was calibrated according to the manufacturer's instructions before sampling. Field readings are presented in the field sampling logs, attached as **Appendix E** and are summarized on **Table 1**. Specific conductance was generally elevated and ORP was generally electronegative, which is consistent with a landfill environment. Turbidity was also elevated (<5 ntu) in nine wells. Purge water in four of these wells was observed to have a color, which likely contributed to the elevated turbidity.

As indicated on the logs, the readings generally stabilized prior to collecting the samples. The samples were collected in hydrochloric acid-preserved 40-ml glass vials with septa caps, nitric-acid preserved 250-mL poly bottles, and non-preserved 1-L amber glass jars, packed in an ice filled cooler, and transported under chain-of-custody protocol to ESS Laboratories for analysis.

Recovered NAPL and purge water was containerized (from wells where NAPL was present) for subsequent off-Site disposal.

5.6.1 Groundwater Sample Analysis

A total of 19 groundwater samples and three trip blanks were collected, packed in an ice chest and transported under chain-of-custody protocol to ESS Laboratory for some or all of the following parameters:

- VOCs via EPA Method 8260B;
- SVOCs via EPA Method 8270C;
- TPH via EPA Method 8100M;
- Pesticides via EPA Method 8081;
- PCBs via EPA Method 8082;
- 15 Solid Waste Metals via EPA Method 6010; and
- Mercury via EPA Method 7470/7471.

5.7 SOIL GAS PROBE INSTALLATION AND SURVEY

Between December 4 and 18, 2019, 13 landfill gas probes were installed along the perimeter of the landfill, outside of the waste footprint, to evaluate potential landfill gas migration beyond the filling limits. One soil gas probe (SG-3) consisted of a 1-inch inner diameter PVC well, installed using direct-push methods utilizing a Geoprobe® rig. The probe was installed at a depth of approximately 10 ft bgs and was screened along the bottom five feet. The probe was equipped with a steel standpipe extending approximately two feet above the existing ground surface and was equipped with a lock and cover system.

The remaining 12 soil gas probes (SG-1, SG-2 and SG-4 to SG-13) consisted of five-foot-long, 0.5-inch inner diameter steel pipes with holes drilled into the bottom 1 foot of pipe. Before installing the soil gas probes, a hand auger was used to evaluate for the presence of waste to a depth of 1.5 ft bgs. If waste was present, the probe was relocated to a location outside of the waste footprint. The soil gas probes were installed at depths of between 1.5 to 4.5 ft bgs, due to refusal. See the soil gas logs provided in **Appendix D** for installation specifications.

Two rounds of soil gas monitoring were conducted for methane (as a percentage of the lower explosive limit-LEL), oxygen, carbon dioxide and hydrogen sulfide. The results of this monitoring are summarized in **Table 2**. The screen section for six of the probes were completely submerged in water. No readings were collected from these probes and groundwater level indicates that gas migration in those areas will be limited, as landfill gas cannot migrate through water. Methane was detected in two probes, SG-3 and SG-4. In SG-3, methane was detected at a level above 100% of the LEL. These two probes are located along the western edge of waste boundary. Additional soil gas probes are needed in this area to evaluate if landfill gas is migrating offsite.

Location	% Methane	% LEL	% Methane	% LEL
	01/14/2020		02/04/2020	
SG-3	16.3	326	0	0
SG-4	2.6	52	4.6	92

5.8 SEDIMENT SAMPLING

Between October 16 and 18, 2019, 11 sediment samples were collected from the wetlands adjacent to the landfill. The sediment sampling locations are shown on **Figure 2**. The sediment samples were collected by hand using a Vibecore-Mini3, a handheld vibracore device. The sediment core tool was driven to three feet below the top of sediment at each of the locations. Three samples from each sediment core were collected from the following depths: 0 to 6 inches, 6 to 18 inches and 18 to 36 inches. These depths were selected to evaluate both potential impacts to benthic invertebrates, which will generally reside in the shallowest sediment and to evaluate historic impacts from landfill operation, which may be present in deeper sediments.

A total of 33 sediment samples and three trip blanks were collected, packed in an ice chest and transported under chain-of-custody protocol to ESS Laboratory. The top two samples (0 to 6 inches and 6 to 18 inches) were submitted for the following laboratory analyses:

- VOCs via EPA Method 8260B;
- SVOCs via EPA Method 8270C;
- TPH via EPA Method 8100M;
- Pesticides via EPA Method 8081;
- PCBs via EPA Method 8082;
- 15 Solid Waste Metals via EPA Method 6010; and
- Mercury via EPA Method 7470/7471.

The 18 to 36-inch sample was placed on hold, to be tested only if significant impacts were observed in the upper two samples. Five of these samples (SSW-4, SSW-5, SSW-7, SSW-9 and SSW-11) were tested due to impacts in shallower samples and to evaluate if deeper impacts were present.

5.9 SURFACE WATER SAMPLING

On December 10, 2019 eleven surface water samples were collected from the wetlands adjacent to the landfill. The surface water sampling locations are shown on **Figure 2**. A total of 11 surface water samples and one trip blank were collected, packed in an ice chest and transported under chain-of-custody protocol to ESS Laboratory for the following parameters:

- VOCs via EPA Method 8260B;
- SVOCs via EPA Method 8270C;
- TPH via EPA Method 8100M;
- Pesticides via EPA Method 8081;
- PCBs via EPA Method 8082;
- 15 Solid Waste Metals via EPA Method 6010;
- Mercury via EPA Method 7470/7471;
- Iron via EPA Method 6010; and
- TOC via EPA Method 9060.

The metals samples were field filtered with a 0.45-micron filter, as metals surface water criteria are generally based on dissolved contaminant levels.

5.10 EXPLORATION LOCATION SURVEY

Exploration location surveys were performed in December 2019 and March 2020. On December 10, 2019 the locations of the sediment and surface water samples were collected by GZA using a Trimble® RI GNSS receiver with 50 cm accuracy. On December 12, 2019 the locations of the wetland flags were collected using a Leica Zeno 20 (L1/L2) Collector with an AS-10

antenna using real-time kinematic (RTK) correction with an accuracy of 1.0 cm horizontal and 2.0 cm vertical. On February 25, 2020 the locations of the GPR anomalies, test pits, monitoring wells and soil gas probes were located using the Leica Zeno 20.

Depth to static groundwater on a Site-wide basis ranged from approximately 3 to 23 feet bgs, based on readings collected in January 2020. Using wellhead elevation survey data collected by GZA on February 25, 2020, groundwater elevations were found to range from 15 to 29 feet in reference to the North American Vertical Datum of 1988 (NAVD 88). Groundwater elevation measurements are summarized in **Table 3** and shown on **Figure 2**. Based on the groundwater elevations, groundwater flow is inferred to flow radially out from the landfill mound to the adjacent wetlands.

We note that localized groundwater flow patterns may vary significantly from those shown due to heterogeneous subsurface conditions, the presence of underground utilities, river elevation changes, and variations in rainfall recharge.

6.0 LABORATORY RESULTS

To evaluate the significance of the analytical data in terms of regulatory criteria, GZA compared the laboratory data to the Method 1 criteria established by current RIDEM Remediation Regulations. Throughout subsequent discussions of the analytical results, the following have been considered and/or assumed:

- The Site is located in a GB-designated resource area; GB Groundwater Criteria and GB Leachability Criteria are applicable; and
- The Site's current and intended future use is commercial, and as such, the I/C-DEC are applicable. Note that cover soils were compared to the RDEC, to evaluate if they may be used as part of a landfill cap.

6.1 DATA VALIDATION AND USEABILITY

GZA performed a modified Tier I Plus data validation/data usability assessment for the groundwater, sediment and surface water data collected as part of this study. This assessment was completed in accordance with the *Region I, EPA-New England Data Validation Functional Guidelines for Evaluating Environmental Analyses (12/96)*. As indicated in the Analytical Data Reports attached in **Appendix F**, all samples were received intact and under appropriately executed chains-of-custody. Based on review of the QA-QC documentation, the following data was qualified:

- In one groundwater data package, the laboratory control sample bromomethane was below the acceptable QA/QC range. As this compound was non-detect in the associated sample (MW-107R) the result was rejected. All other sample results were accepted without qualifications.
- Methylene chloride (a common laboratory contaminant) was detected in the Trip Blank for certain sediment samples. Methylene chloride was detected at low concentrations below the level detected in the Trip Blank in seven of the associated sediment samples. The results for this compound have therefore been reported as undetected (U).
- In the laboratory control sample for sediment sample SSW-4 6-18in, dichlorodifluoromethane was below the acceptable QA/QC range. As this compound was non-detect in the associated sample (SSW-4 6-18in) the result was rejected.
- All other sample results were accepted without qualification.

6.2 COVER SOIL ANALYTICAL RESULTS

A total of three cover soil samples and two trip blanks were collected and submitted for analytical testing. Analytical results are shown in **Table 4**. No VOCs or SVOCs were detected above the method reporting limit (MRL) in any of the samples or trip blanks. Various metals were detected above the MRL in all three samples, but were well below RIDEM's I/C-DEC and RDEC.

6.3 GROUNDWATER ANALYTICAL RESULTS

A total of 19 groundwater samples and three trip blanks were collected and submitted for analytical testing. A detailed description of the contaminants encountered is presented below. Analytical results are shown in **Table 5**. Note that while groundwater at the Site and the surrounding area are classified as a GB resource, exceedences of the GA Groundwater Objective are also discussed below for comparison purposes only.

6.3.1 VOCs

Two VOCs were detected above RIDEM's GB Groundwater Objectives, each in one well; ethylbenzene in MW-EA-01 (inside the waste footprint) and vinyl chloride in MW-101 (outside of the waste footprint). Benzene and chlorobenzene were also detected above RIDEM's GA Groundwater Objective in 12 wells and 2 wells, respectively. Various other VOCs were detected above the MRL, but below the applicable GA and GB Groundwater Objectives.

6.3.2 SVOCs

One SVOC, bis(2-Ethylhexyl)phthalate, was detected in eight samples at concentrations above the GA Groundwater Objective (no GB Groundwater Objectives have been established for SVOCs). All other SVOCs were below the MRL and/or the GA Groundwater Objective.

6.3.3 TPH

TPH was detected in 17 samples at concentrations ranging from 0.5 to 20.3 mg/L; there are no applicable GA or GB Groundwater Objectives for TPH.

6.3.4 Metals

Arsenic was detected in one sample, cadmium in two samples, lead in four samples and nickel in two samples at concentrations above the applicable GA Groundwater Objectives. All other sample results were below the GA Groundwater Objectives or non-detect. We note that no GB Groundwater Objectives have been established for metals.

6.3.5 Pesticides

Five pesticides (4,4'-DDD, alpha-Chlordane, gamma-Chlordane, Total Chlordane, and methoxychlor) were detected at concentrations greater than the MRL, but below the GA Groundwater Objectives.

6.3.6 PCBs

Aroclor 1242 was detected in seven samples above the MRL, with three of the samples detected at concentrations above the GA Groundwater Objective. Aroclor 1254 was detected in three samples above the MRL, with one of the samples detected at a concentration above the GA Groundwater Objective. Aroclor 1260 was detected in one sample above the GA Groundwater Objective. All other PCBs results were below the MRL. Again, no GB Groundwater Objectives have been established for PCBs.

6.3.7 MW-3 Area LNAPL/PCB Evaluation

An approximately 0.81-foot thick layer of LNAPL was present in MW-3 at 20.5 ft bgs; and an approximately 0.70-foot thick layer of LNAPL was present in MW-EA-01 at 17.7 ft bgs. LNAPL has historically been observed been observed in both of these wells. LNAPL was not encountered in the four new wells (MW-109 to MW-112) installed around MW-3 to assess the aerial extent of LNAPL in the area.

Benzene was detected in all six samples, at concentrations above RIDEM's GA Groundwater Objective. Ethylbenzene was also detected above RIDEM's GA and GB Groundwater Objectives in MW-EA-01. The SVOC bis(2-Ethylhexyl)phthalate was detected in five samples (MW-3, MW-EA-01, MW-110, MW-111 and MW-112) at concentrations above RIDEM's GA Groundwater Objective. All other VOC and SVOC results were below GA and GB Groundwater Objectives in samples from these landfill interior wells.

TPH was detected at levels ranging from 1.65 mg/L in MW-112 to 20.3 mg/L in MW-EA-01; there are no GA or GB Groundwater Objectives for TPH. The PCB Aroclor 1242 was detected in samples from wells MW-3, MW-EA-01, MW-110 and MW-111 at concentrations above the MRL, with the concentration detected in MW-EA-01 exceeding the GA Groundwater Objective. Aroclor 1260 was also detected in MW-EA-01 at a concentration above the GA Groundwater Objective. Aroclor 1254 was also detected in MW-3 above the MRL, but below the GA Groundwater Objective. All other PCB and Pesticide results were below the MRL.

6.4 SEDIMENT ANALYTICAL RESULTS

A total of 33 sediment samples (11 locations with samples taken from 0 to 6 inches, 6 to 18 inches and 18 to 36 inches) and three trip blanks were collected. The top two samples from each location were submitted for laboratory analysis and the bottom sample was placed on hold, to be tested only if significant impacts were observed in the upper two samples. Five of the bottom samples were analyzed due to impacts in shallower samples and to evaluate if deeper impacts were present. A detailed description of the contaminants encountered is presented below. Analytical results are shown in **Table 6**.

Sediment data in **Table 6** is compared to Threshold Effects Concentration (TEC) Freshwater Screening Criteria representing concentrations at or below which adverse effects are not expected. Sediment concentrations were also compared to Probable Effect Concentration (PEC) Freshwater Screening Criteria, which are concentrations that have been detected in sediments that have often been associated with adverse effects to benthic organisms[1]. Note that these screening levels are not regulatory criteria and are provided as a point of comparison for ecological risk screening purposes only.

It has become widely recognized that many TECs are very conservative values that are often comparable to background, and such concentrations often do not pose a significant risk of harm. For this reason, for example, Massachusetts Department of Environmental Protection (MassDEP) has adopted the PECs as their screening values for most metals, rather than the TECs. MassDEP's decision was based on experience with many risk assessments for which toxicity testing showed that concentrations comparable to TECs were not toxic to benthic organisms. Comparing sediment concentrations to PECs is often more helpful in focusing the evaluation on sediment conditions that have a higher potential to cause toxic effects. As such, exceedences of TEC Freshwater Screening Criteria are included in **Table 6** for comparison purposes and only PEC Freshwater Screening Criteria exceedences are discussed in this report.

6.4.1 VOCs

Only three VOCs (1,4-dichlorobenzene, chlorobenzene and methylene chloride) were detected in the samples, all were observed at concentrations significantly below RIDEM's R-DEC, I/C-DEC and Freshwater Sediment Screening Criteria (PECs). All other VOCs results were below the MRL.

[1] The Freshwater Sediment Screening Criteria are a compilation of ecological screening benchmarks from USEPA Region 5, Threshold Effect Concentrations (TEC) presented in MacDonald et al. 2000, Freshwater Sediment Quality Guidelines from MacDonald et al. 1999 and Freshwater Sediment Guidelines from NOAA Sediment Quick Reference Tables (SQUIRTs).

6.4.2 SVOCs

Various SVOCs were detected in several samples in the 0 to 6-inch and the 6 to 18-inch samples at concentrations below RIDEM's R-DEC, I/C-DEC and PEC Freshwater Sediment Screening Criteria (including the PEC for total PAHs). All SVOCs in the 18 to 36-inch samples were below their MRLs.

6.4.3 TPH

TPH was detected in five locations in the 0 to 6-inch range and one location in the 6 to 18-inch range at concentrations below RIDEM's R-DEC, I/C-DEC and Freshwater Sediment Screening Criteria. All other TPH results were below the MRL.

6.4.4 Metals

Arsenic was detected above RIDEM's I/C-DEC in SSW-5 (6 to 18 inches), SSW-6 (0 to 6 inches), SSW-8 (0 to 6 inches) and SSW-11 (6 to 18 inches). Note that RIDEM's arsenic I/C DEC is below the PEC Freshwater Screening Criteria of 33 mg/kg and no exceedences of the PEC were observed.
All other sample results were below RIDEM's R-DEC, I/C-DEC and Freshwater Sediment Screening Criteria or non-detect.

6.4.5 Pesticides

One pesticide (4,4'-DDE) was detected in the 6 to 18 inch sample at concentrations greater than the PEC Freshwater Sediment Screening Criteria in sediment sample SSW-11, the most downgradient location which includes contributions from non-landfill sources, i.e., this location accepts stormwater flows from the adjacent TF Green Airport. Chlordane, alpha-chlordane and gamma-chlordane were also detected in sediment sample SSW-2 in the 0 to 6-inch sample at a concentration above RIDEM's RDEC and/or the PEC Freshwater Sediment Screening Criteria. All other sample results were below RIDEM's R-DEC, I/C-DEC and Freshwater Sediment Screening Criteria or non-detect.

6.4.6 PCBs

All PCBS results were below the MRL for all locations and depths.

6.5 SURFACE WATER ANALYTICAL RESULTS

A total of 11 surface water samples and three trip blanks were collected and submitted for analytical testing. A detailed description of the contaminants encountered is presented below. Analytical results are shown in **Table 7**.

6.5.1 VOCs

Chlorobenzene was detected in SSW-9 at a concentration exceeding RIDEM's Freshwater Aquatic Chronic Criteria (FWCC). Various other VOCs were also detected in SSW-5, SSW-6, SSW-7, SSW-8 and SSW-9 at concentrations below RIDEM's FWCC. All other VOCs results were below the MRL.

6.5.2 SVOCs

Two exceedances of RIDEM's FWCC (naphthalene and 1,4-dichlorobenzene) were noted in SSW-9. All other sample results were below RIDEM's Water Quality Criteria or non-detect.

6.5.3 TPH

TPH was detected in nine samples at concentrations ranging from 0.2 to 1.52 mg/L; there is no applicable State Water Quality Criteria for TPH.

6.5.4 Dissolved Metals

Iron was detected in six samples, cadmium in one sample, nickel in one sample and zinc in three samples at concentrations exceeding RIDEM's FWCC. Cadmium was also detected in one sample (SSW-6) above RIDEM's Acute Ambient Water Quality Criteria. All other sample results were below the State Water Quality Criteria or non-detect.

6.5.5 Pesticides

All pesticide results were below the MRL for all locations.

6.5.6 PCBs

Aroclor 1242 was detected in surface water sample SSW-9 at a concentration exceeding the RIDEM's FWCC. All other PCBs results were non-detect.

6.6 SCREENING LEVEL ECOLOGICAL RISK ASSESSMENT (SCLERA)

As described in the sections above, GZA compared sediment and surface water data to relevant and/or applicable ecological screening criteria (PEC ecological sediment screening benchmarks and AWQC, respectively). One pesticide (4,4'-DDE) was detected in the 6 to 18-inch at a concentration greater than the PEC Freshwater Sediment Screening Criteria in SSW-11. This is the most downgradient sediment and surface water sampling location and conditions here likely include contributions from non-landfill sources. Chlordane, alpha-chlordane and gamma-chlordane were also detected above the PEC Freshwater Screening Criteria in the SSW-3 0 to 6-inch sample All other SVOCs, metals and pesticides, and all VOCs and PCBs were below the Freshwater Sediment Screening Criteria or non-detect.

Chlorobenzene was detected in surface water sample SSW-9 at a concentration exceeding RIDEM's FWCC. Two SVOCs (1,4-Dichlorobenzene and naphthalene) were detected in SSW-9 at concentrations exceeding RIDEM's FWCC. Iron was detected in six samples, cadmium in one sample, nickel in one sample and zinc in three samples at concentrations exceeding RIDEM's FWCC. One cadmium exceedance of RIDEM's Freshwater Aquatic Acute Criteria was also observed. Aroclor 1242 was detected in SSW-9 at a concentration exceeding the RIDEM's FWCC. All other VOCs, SVOCs, dissolved metals, pesticides and PCBs were below RIDEM's Water Quality Criteria or non-detect.

It is GZA's opinion that there is a low potential for significant risk of harm to ecological receptors in the adjacent wetlands. This opinion is based on comparing contaminant concentrations in surface water and sediment samples to ecological screening benchmarks. These comparisons indicate that:

- For surface water, exceedances are largely limited to dissolved iron in samples from six locations, dissolved cadmium in one location and dissolved zinc at three locations. Because iron in surface water occurs in complexes with low bioavailability, the water quality benchmark for iron is a relatively poor predictor of toxicity. The magnitude of exceedances by zinc was relatively low for two sample, however, 1.31 mg/l of zinc detected in SSW-6 is 22 times higher than the chronic water quality benchmark. If this higher concentration is typical, dissolved zine may be causing significant risk to aquatic receptors in the vicinity of SSW-6 sampling location. As discussed in Section 8.00, a long-term surface water sampling program is planned for the adjacent wetland area. Those data will allow a better assessment of the potential risk posed by iron, zinc, and other contaminants of concern; and

- For sediment, there were relatively few exceedances of the PECs, and the locations of exceedances were scattered throughout the area sampled. Sediment benchmark exceedances did not show a pattern that might indicate particular areas, or larger areas that may present a greater concern. It is GZA's opinion that additional evaluation of potential ecological risks from sediment contaminants is not warranted given the relatively few sediment benchmark exceedances, the small magnitude of the exceedances, and no pattern of exceedances that would suggest potentially significant exposures of benthic organisms over areas large enough to be represented by more than one sample location. Summary and Conclusions

7.0 SUMMARY AND CONCLUSIONS

This *Site Investigation*, conducted for property identified as the Former Truk-Away Landfill on Warwick Industrial Drive in Warwick, RI (the Site), was performed for the Truk-Away Landfill Joint Defense Group to address the requirements of two RIDEM regulatory programs: the Solid Waste Program (due to the former use of the property as a solid waste disposal facility) and the Site Remediation Program (due to the Site's CERCLIS designation). The investigation involved the collection, screening and/or laboratory testing of soil gas, soil, groundwater, sediment and surface water samples by GZA. Based on our evaluation of the project data, the following observations and conclusions have been developed.

- The Site contains a former unlined landfill that operated from 1970 to 1978. While in operation, the landfill accepted, household, industrial, institutional, commercial and hazardous waste.

- The Site is located at the end of Warwick Industrial Drive in Warwick, RI and is owned by the RIAC. Approximately 36 acres of the 54-acre property is occupied by the unlined municipal landfill.

- In general, cover soils encountered in test pits were observed to consist of sand with varying degrees of gravel and silt. Generally, the cover soil thickness was observed to be between 1 and 2 feet. Only three locations had an existing cover soil thickness of > 2 feet. Laboratory analyses of these three locations showed no exceedances of the RIDEM's R-DEC.

- Solid waste was observed in test pits located around the perimeter of the southern and northern suspected waste footprint, at depths ranging from 0-3 ft bgs. Generally, the observed edge of waste is consistent with the previous delineations. On the landfill perimeter, especially the northeastern side of the landfill, waste appears to have been deposited into the wetland area.

- Landfill gas containing levels of methane above RIDEM's criteria of 25% of the LEL were observed in samples from two perimeter monitoring probes along the western edge of waste boundary. Additional soil gas probes will be required in this area to evaluate if landfill gas is migrating offsite.

- Groundwater at the Site is present at depths of between approximately 3 to 23 feet bgs. The surveyed elevations of the monitoring well network indicate that groundwater flows radially out from the landfill mound to the adjacent wetlands. Note that groundwater appears to be mounded within the landfill.

- A total of 19 wells, seven existing and 12 newly installed, were sampled and submitted for analytical testing of VOCs, SVOCs, TPH, Pesticides, PCBs, 15 solid waste metals and mercury. The resultant data, when compared to the RIDEM's GA Groundwater Objectives, indicated exceedances for certain VOCs (benzene, chlorobenzene, ethylbenzene or vinyl chloride), the SVOC bis(2-Ethylhexyl)phthalate, PCBs and/or certain metals (arsenic, cadmium, lead and nickel) in each of the sampled wells. The only detected GB Groundwater Objective exceedences were for ethylbenzene and vinyl chloride, each in one well.

- An approximately 0.81-foot thick layer of LNAPL was present in MW-3 and an approximately 0.70-foot thick layer of LNAPL was present in MW-EA-01. LNAPL has historically been observed in both of these wells. LNAPL was not encountered in the four new wells (MW-109 to MW-112) installed around MW-3 to assess the aerial extent of LNAPL in the area.

- A total of 33 sediment samples (11 locations with samples taken from 0 to 6 inches, 6 to 18 inches and 18 to 36 inches bgs) were collected. The top two samples from each location as well the bottom sample from five locations were submitted for laboratory analysis of VOCs, SVOCs, TPH, Pesticides, PCBs, 15 solid waste metals and mercury. Laboratory results showed limited exceedences of the RIDEM's R-DEC for arsenic in the top six inches and limited exceedences of ecological screening criteria for pesticides, in the top 18-inches of sediment.

- A total of 11 surface water samples were collected and submitted for analytical testing of VOCs, SVOCs, TPH, Pesticides, PCBs, 15 solid waste metals, mercury, iron and TOC. Laboratory results showed exceedences for State Water Quality Criteria for chlorobenzene in one sample, SVOCs in one sample, iron in each of the eleven samples (including the background sample) cadmium in one sample, nickel in one sample and zinc in three samples.

- It is GZA's opinion that there is a low potential for significant risk of harm to ecological receptors in the adjacent wetlands. This opinion is based on comparing contaminant concentrations in surface water and sediment samples to ecological risk screening benchmarks.

8.0 EVALUATION OF REMEDIAL ALTERNATIVES

To address the requirements of Section 1.8.4 of the Remediation Regulations, GZA has evaluated three conceptual remedial alternatives for the Site. In developing these remedial alternatives, we have taken into consideration the following:

- Groundwater at the Site and the surrounding area is classified as GB;
- PCB containing LNAPL is present within waste;
- The landfill has not yet been properly closed in accordance with applicable regulatory requirements;
- Landfill cover material thicknesses and minimum slope requirements (e.g., ponded water exists within the landfill footprint) need to be addressed;
- The groundwater data shows on-Site and downgradient exceedances of GA, and in limited cases GB, Groundwater Objectives. Note that groundwater at the Site and the surrounding area are classified as a GB resource; the nearest GA resource is 0.9 miles east of the Site;
- Landfill gas exceeded 100% of the LEL along the western landfill perimeter; and
- Limited ecological risk is present in abutting wetlands (surface water and sediment)

The following three remedial alternatives were developed to address the above issues:

Alternative #1 - No Action Alternative: This alternative results in no institutional controls or active remedial measures. This does not address the presence of the former landfill, as municipal solid waste is present over much of the Site or any of the observed impact to environmental media. As such, the "no further action" alternative is not considered protective of human health and the environment; and does not address applicable regulatory requirements.

Alternative #2 – Institutional Controls: Under this alternative, an Environmental Land Use Restriction (ELUR) as outlined in Section 1.9.9 of the Remediation Regulations could be placed on the property, prohibiting future groundwater use and limiting land use to industrial/commercial activities. However, this does not address the current landfill conditions (i.e., both steep and flat slopes, poor drainage, etc.) or impacts to various environmental media. Simply limiting the property use to industrial/commercial

development and precluding groundwater use will not address all potential contaminant exposure pathways and does not provide full regulatory compliance. As such, institutional controls alone are not considered a viable remedial alternative.

Alternative #3 – *Site Capping and Institutional Controls*: This third, and recommended, alternative includes the remedial actions described above in Alternative 2 (Institutional Controls consisting of an ELUR) landfill capping and long term environmental monitoring. This alternative involves a combination of remedial measures and incorporates requirements of the applicable Site Remediation and Solid Waste regulatory programs. This alternative consists of:

Landfill Capping

1. Low Permeability Soil Cap - Install a cap over the landfill so that all areas of the Site that received solid waste are provided with a cap thickness of not less than 2 feet. In order to limit infiltration through the soil cap, we propose the following cap cross-section from bottom to top:

    - Existing soil, waste and borrow soils will be graded to meet subgrade slope requirements;
    - Install a permeable geotextile warning barrier to prevent direct exposure to waste and contaminated soils;
    - Place 18 inches of low permeability soil ($1x10^{-4}$ cm/sec maximum hydraulic conductivity); and
    - Cover with 6 inches of plantable soil/topsoil, seeded to establish vegetative cover.

    Waste deposited within wetland areas will remain in place and will not be capped. The cap design will incorporate passive or active LFG vents, 1 per acre, to limit the lateral migration of methane and other volatile contaminants.

    The source of the cover material for use above the permeable geotextile will be evaluated to demonstrate that it does not contain contaminants at concentrations above the Method 1 R-DEC. Existing cover soils may be utilized in the final cap if they meet the R-DEC and existing cover soils and waste may be used for shaping and grading of the cap subgrade. This activity may require an approved beneficial use determination (BUD) from RIDEM.

    This will address the regulatory requirement to properly close the landfill and mitigate any direct exposure risk associated with contact with waste or contaminated soils, if present.

2. Re-grade the Site, or portions thereof, to meet minimum drainage slope (i.e., 3% to 5%) and maximum stable slope (i.e., 3:1) requirements of Section 2.2.12 of the Solid Waste Regulations No. 2.

    This action will help to control soil erosion, reduce infiltration of precipitation, eliminate ponded/perched water and associated leachate generation, and manage stormwater drainage.

ELUR

To protect the long-term effectiveness of the remedy RIDOA will establish an ELUR for the property. The ELUR will serve to:

- Restrict the property's use from any residential development;
- Require that the Site's landfill cap and other engineered controls remain in good condition;
- Prohibit the use of groundwater at the Site for drinking water;
- Contain a Soil Management Plan (SMP) for any post-closure soil disturbance;
- Provide for annual inspection by an Environmental Professional; and
- Existing soil, waste and borrow soils will be graded to meet subgrade slope requirements.

LFG Migration Evaluation

We will further evaluate gas migration on the western side of the landfill through the installation and monitoring of additional probes. This investigation will focus on areas west of SG-3 and SG-4, where methane levels above 100% of the LEL was observed. This will be conducted as part of a Limited Design Investigation (LDI).

Cesspool/Dry Well

A cesspool/dry well was located by the GPR survey/test pit program on the western portion of the landfill, in the vicinity of the former onsite building. This requires further investigation (borings and monitoring wells) and soil/groundwater testing. This will be conducted as part of an LDI. As part of this work, we will resample the LNAPL in MW-3 MW-EA-01 for PCBs for comparison to TSCA's 50 ppm limit.

Environmental Monitoring

An environmental monitoring program (EMP), which incorporates, to the extent practical, the monitoring wells and soil gas probes installed as part of the SIR will be developed. The groundwater sampling program will incorporate the use of EPA's Low-Flow well purging and sampling protocols. The analytical program will include the organic and inorganic target analytes identified in Appendix A of RIDEM's Solid Waste Regulations No. 2. According to these regulations (Section 2.1.9), groundwater monitoring needs to be performed at the Site for 30 years. We propose that monitoring be conducted quarterly during closure and for 2 years following closure. Thereafter, the frequency should be reduced to semi-annual and then annual (assuming the data supports such a reduction in monitoring frequency). The groundwater monitoring program will include certain scheduled milestones at which the frequency of the sampling can be re-evaluated.

As part of groundwater monitoring, LNAPL (where observed) will be manually bailed and containerized on a quarterly basis.

A surface water monitoring program will be conducted in conjunction with the groundwater monitoring program, to evaluate changes in surface water concentrations over time.

Perimeter soil gas monitoring will be performed in conjunction with the groundwater monitoring program. Soil gas monitoring will include field screening for total volatile organics via PID screening, H_2S, and Methane as LEL.

The EMP will be used to assess the effectiveness of landfill capping and source control on reducing groundwater contaminant concentrations both on- and off-Site. Additionally, the perimeter soil gas monitoring will be used to evaluate the effectiveness of the passive landfill gas venting at limiting lateral methane and VOC migration, and to assess the need for active migration control.

9.0 RECOMMENDED REMEDIAL ALTERNATIVE

Alternative #3, is the recommended remedial alterative for the Site. In proposing this alternative, it is GZA's opinion that this Alternative is consistent with the current and foreseeable reuse of the Site and mitigates current and future risks from identified onsite contamination and off-Site mitigation.

10.0 CERTIFICATIONS

To address Rule 1.8.5 of the Remediation Regulations, the following statements of certification are provided.

GZA GeoEnvironmental, Inc. certifies to the best of its knowledge, that this Site Investigation Report is complete and accurate.

Edward A. Summerly, P.G.
Principal / District Office Manager
GZA GeoEnvironmental, Inc

As a designee of the Truk-Away Landfill Joint Defense Group, I certify, to the best of my knowledge, that this Site Investigation Report is a complete and accurate representation of the Site and the release, and contains all known facts surrounding the release.

Michael P. Donegan, ESB/RAC

SG-13	--	--	--	--	--	--	--	--	--	--	--

Notes

1. The readings were collected using a LANDTEC GEM5000.
2. Landfill gas measurements could not be taken from SG-2, SG-6, SG-7, SG-8 or SG-13 due to standing water present in the probe.
3. CO readings were not taken during the 1/14/2020 round because the rental meter did not have a CO probe.

Notes:
1: For the complete list of target analytes refer to the attached laboratory certificates of analysis.
2. Bold values indicate the constituent was detected above the laboratory reporting limit. Orange highlight indicates an exceedence of RIDEM's GB Leachability Criteria. Yellow highlight indicates an exceedance of RIDEM's I/C DEC Criteria. Green highlight indicates an exceedance of RIDEM's R-DEC Criteria.
3. "U" indicates that the parameter is not detected.
4. "NE" indicates that a standard for the parameter is not established.
5. ND indicates that the paramater is not detected.
6. NT indicates that the paramater was not tested for.

Notes:
1: For the complete list of target analytes refer to the attached laboratory certificates of analysis.
2. Bold values indicate the constituent was detected above the laboratory reporting limit.
Yellow highlight indicates an exceedance of RIDEM's GA Groundwater Quality Criteria. Orange highlight indicates an exceedance of RIDEM's GB Groundwater Quality Criteria.
3. "U" indicates that the parameter is not detected.
4. "P" indicates that the percent difference between primary and confirmation laboratory results exceeds 40%.
5. "LC" indicates that the lower value is used due to matrix interferences.
6. "NE" indicates that a standard for the parameter is not established.
7. "ND" indicates that the parameter is not detected.
8. "NT" indicates that the parameters was not tested.

Notes:
1: For the complete list of target analytes refer to the attached laboratory certificates of analysis.
2. Bold values indicate the constituent was detected above the laboratory reporting limit.
Yellow highlight indicates an exceedance of RIDEM's GA Groundwater Quality Criteria. Orange highlight indicates an exceedance of RIDEM's GB Groundwater Quality Criteria.
3. "U" indicates that the parameter is not detected.
4. "P" indicates that the percent difference between primary and confirmation laboratory results exceeds 40%.
5. "LC" indicates that the lower value is used due to matrix interferences.
6. "NE" indicates that a standard for the parameter is not established.
7. "ND" indicates that the parameter is not detected.
8. "NT" indicates that the parameters was not tested.

Notes:
1: For the complete list of target analytes refer to the attached laboratory certificates of analysis.
2. Bold values indicate the constituent was detected
3. Green highlight indicates an exceedence of
4. Yellow highlight indicates an exceedance of
5. Orange highlight indicates an exceedance of the
6. "NE" indicates that a standard for the parameter is not established.
7. "U" indicates that the parameter is not detected.
8. "J" indicates that the parameter is Reported between MDL and MRL
9. "D" indicates that the parameter was diluted
10. "NT" indicates that the parameter was not tested.
11. "P" indicates that the percent differece between primary and confirmation results exceeds 40%.
12. "LC" indicates that the lower value is used due to matrix interferences.
13. The Freshwater Sediment Screening Criteria (TECs and PECs) are a compilation of ecological screening benchmarks from USEPA Region 5, Threshold Effect Concentrations (TEC) presented in MacDonald et al. 2000, Freshwater Sediment Quality Guidelines from MacDonald et al. 1999 and Freshwater Sediment Guidelines from NOAA Sediment Quick Reference Tables (SQUIRTs). Benchmarks shown for gamma-chlordane and alpha-chlordane are the benchmarks presented for chlordane.

Notes:
1: For the complete list of target analytes refer to the attached laboratory certificates of analysis.
2. Bold values indicate the constituent was detected above the laboratory reporting limit.
3. Blue highlight indicates an exceedance of RIDEM's Acute Freshwater Aquatic Life Criteria.
4. Green highlight indicates an exceedence of RIDEM's Freshwater Chronic Aquatic Life Criteria.
5. "NE" indicates that a standard for the parameter is not established.
6. "U" indicates that the parameter is not detected.
7. "D" indicates that the parameter was diluted
8. "NT" indicates that the parameter was not tested.
9. "*" indicates criteria applicable only for freshwaters in which the pH is between 6.5 and 9.
10. "$" indicates that the aquatic life criteria for these values were issued in 1980 utilizing the 1980 Guidelines for criteria development. The acute values shown are final acute values which, by the 1980 Guidelines, are instantaneous values as contrasted with a Criteria Maximum Concentration (CMC) which is a one-hour average.
11. Water Quality Criteria is hardness dependent and was calculated based on a hardness of 43 mg/L, which was the average dry weather hardness at station AP01 from water quality monitoring data provided by RIDEM, from water quality monitoring associated with Buckeye Brook. RIDEM Station AP01 is collocated with sampling location SSW-11. Cadmium values based on updated EPA formula.
12. Water Quality Criteria is pH dependent and was calculated based on a pH of7.1, which was the average dry weather hardness at station AP01 from water quality monitoring data provided by RIDEM, from water quality monitoring associated with Buckeye Brook. RIDEM Station AP01 is collocated with sampling location SSW-11.

APPENDIX A

LIMITATIONS

USE OF REPORT

1. GZA GeoEnvironmental, Inc. (GZA) prepared this report on behalf of, and for the exclusive use of our Client for the stated purpose(s) and location(s) identified in the Proposal for Services and/or Report. Use of this report, in whole or in part, at other locations, or for other purposes, may lead to inappropriate conclusions; and we do not accept any responsibility for the consequences of such use(s). Further, reliance by any party not expressly identified in the agreement, for any use, without our prior written permission, shall be at that party's sole risk, and without any liability to GZA.

STANDARD OF CARE

2. GZA's findings and conclusions are based on the work conducted as part of the Scope of Services set forth in the Proposal for Services and/or Report and reflect our professional judgment. These findings and conclusions must be considered not as scientific or engineering certainties, but rather as our professional opinions concerning the limited data gathered during the course of our work. Conditions other than described in this report may be found at the subject location(s).

3. GZA's services were performed using the degree of skill and care ordinarily exercised by qualified professionals performing the same type of services, at the same time, under similar conditions, at the same or a similar property. No warranty, expressed or implied, is made. Specifically, GZA does not and cannot represent that the Site contains no hazardous material, oil, or other latent condition beyond that observed by GZA during its study. Additionally, GZA makes no warranty that any response action or recommended action will achieve all of its objectives or that the findings of this study will be upheld by a local, state or federal agency.

4. In conducting our work, GZA relied upon certain information made available by public agencies, Client and/or others. GZA did not attempt to independently verify the accuracy or completeness of that information. Inconsistencies in this information which we have noted, if any, are discussed in the Report.

SUBSURFACE CONDITIONS

5. The generalized soil profile(s) provided in our Report are based on widely-spaced subsurface explorations and are intended only to convey trends in subsurface conditions. The boundaries between strata are approximate and idealized, and were based on our assessment of subsurface conditions. The composition of strata, and the transitions between strata, may be more variable and more complex than indicated. For more specific information on soil conditions at a specific location refer to the exploration logs. The nature and extent of variations between these explorations may not become evident until further exploration or construction. If variations or other latent conditions then become evident, it will be necessary to reevaluate the conclusions and recommendations of this report.

6. Water level readings have been made, as described in this Report, in and monitoring wells at the specified times and under the stated conditions. These data have been reviewed and interpretations have been made in this report. Fluctuations in the level of the groundwater however occur due to temporal or spatial variations in areal recharge rates, soil heterogeneities, the presence of subsurface utilities, and/or natural or artificially induced perturbations. The observed water table may be other than indicated in the Report.

COMPLIANCE WITH CODES AND REGULATIONS

7. We used reasonable care in identifying and interpreting applicable codes and regulations necessary to execute our scope of work. These codes and regulations are subject to various, and possibly contradictory, interpretations. Interpretations and compliance with codes and regulations by other parties is beyond our control.

SCREENING AND ANALYTICAL TESTING

8. GZA collected environmental samples at the locations identified in the Report. These samples were analyzed for the specific parameters identified in the report. Additional constituents, for which analyses were not conducted, may be present in soil, groundwater, surface water, sediment and/or air. Future Site activities and uses may result in a requirement for additional testing.

9. Our interpretation of field screening and laboratory data is presented in the Report. Unless otherwise noted, we relied upon the laboratory's QA/QC program to validate these data.

10. Variations in the types and concentrations of contaminants observed at a given location or time may occur due to release mechanisms, disposal practices, changes in flow paths, and/or the influence of various physical, chemical, biological or radiological processes. Subsequently observed concentrations may be other than indicated in the Report.

INTERPRETATION OF DATA

11. Our opinions are based on available information as described in the Report, and on our professional judgment. Additional observations made over time, and/or space, may not support the opinions provided in the Report.

ADDITIONAL INFORMATION

12. In the event that the Client or others authorized to use this report obtain additional information on environmental or hazardous waste issues at the Site not contained in this report, such information shall be brought to GZA's attention forthwith. GZA will evaluate such information and, on the basis of this evaluation, may modify the conclusions stated in this report.

ADDITIONAL SERVICES

13. GZA recommends that we be retained to provide services during any future investigations, design, implementation activities, construction, and/or property development/ redevelopment at the Site. This will allow us the opportunity to: i) observe conditions and compliance with our design concepts and opinions; ii) allow for changes in the event that conditions are other than anticipated; iii) provide modifications to our design; and iv) assess the consequences of changes in technologies and/or regulations.

Work Assignment No. 23-1JZZ
Document No. 7710-023-FR-BGMM

INTRODUCTION

The CDM Federal Programs Corporation (CDM) Alternative Remedial Contracting Strategy (ARCS) team was requested by the U.S. Environmental Protection Agency (EPA) Region I Waste Management Division to perform a Site Inspection Prioritization (SIP) of the Truk-Away Landfill property in Warwick, Rhode Island. Tasks were conducted in accordance with the ARCS Contract No. 68-W9-0045, SIP scope of work dated September 3, 1992, and technical specifications provided by EPA under Work Assignment No. 23-1JZZ, which was issued to CDM on September 22, 1992. A Site Inspection was prepared by Ecology and Environment, Inc. in June 1982. On the basis of the information provided in the Site Inspection report, the Truk-Away Landfill SIP was initiated.

Background information used in the generation of this report was obtained through file searches conducted at Rhode Island Department of Environmental Management (RIDEM), Rhode Island Department of Administration, telephone interviews, conversations with persons knowledgeable of the Truk-Away Landfill, and conversations with other federal, state, and local agencies. Additional information was collected during the CDM onsite reconnaissance on March 10, 1993 and environmental sampling on May 11, 1993.

This package follows the guidelines developed under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980, as amended, commonly referred to as Superfund. However, these documents do not necessarily fulfill the requirements of other EPA regulations such as those under the Resource Conservation and Recovery Act (RCRA) or other federal, state or local regulations. SIPs are intended to provide a preliminary screening of sites to facilitate EPA's assignment of site priorities. They are limited efforts and are not intended to supersede more detailed investigations.

SITE DESCRIPTION

The Truk-Away Landfill is located on Industrial Drive in Warwick, Kent County, Rhode Island (Latitude 41° 34′ 50″ N, Longitude 71° 25′ 20″ W) (see Figure 1: Location Map) [59]. The actual landfill comprises approximately 36 acres of a 52-acre parcel and is located approximately 3 miles west of Narragansett Bay, 2 miles north of Greenwich Bay and is adjacent to the Theodore Francis Green Memorial State Airport southeast runway [2,15]. The property is identified as Plat 342, Lots 2,3,5, and 429 in the City of Warwick Land Evidence Records [3]. The landfill is zoned light industrial [7]. The land in the area adjacent to Sandy Lane is generally zoned for residential use; some areas near the site have been developed for light industry [11]. The property is bordered to the southeast by the old Warwick City Dump (no longer operating), to the south by a residential area, to the west by the former Leesona Corporation, to the north by the airport runway, and to the east by wetlands [2].

There are no buildings on the property, but concrete slabs near the main entrance indicate the location of former buildings onsite. A dirt road crosses the landfill. Varying depths of fill throughout the landfill are evidenced by rises and slopes and exposed trash and debris (medical waste, paint cans, crushed drums, electrical waste, mercury film packs) scattered across the property. A dark oily area is located near the concrete slabs [2].

An 8-foot fence topped with barbed wire surrounds the property and concrete Jersey barriers prevent access to the main entrance. Tires, used oil, and other solid waste have been illegally dumped along Industrial Drive just outside the main entrance. Access to the landfill is not limited near the residential area located south of the property due to an estimated 25-foot wide opening in the landfill's fence. Well-worn dirt bike trails extend into the landfill from the end of Bartlett Drive [2].

Figure 2

OPERATIONAL AND REGULATORY HISTORY AND WASTE CHARACTERISTICS

The earliest known use of the property was a sand and gravel operation [2,59]. W.J. Realty Co. of Providence, Rhode Island owned and leased the landfill property to Truk-Away of Rhode Island, Inc. (previously Sanitas Disposal Co.) from 1969 to 1976-1977 when it was sold to Truk-Away of Rhode Island, Inc. (owned by Charles Wilson) [2,53]. Rhode Island Department of Transportation (RIDOT) Division of Airports took ownership of the property on October 25, 1977 [3].

The property began accepting municipal and industrial wastes in 1970 under the name Warwick Sanitary Landfill, operated by Sanitas Waste Disposal of Rhode Island, a private commercial refuse collection company [56]. By 1976, the company had changed its name to Truk-Away of Rhode Island, Inc., and the landfill became known as the Truk-Away Landfill [25,62]. Along with its landfill operation, Truk-Away of Rhode Island, Inc. was (is) a major hauler of commercial and industrial trash in Warwick (14).

During a State inspection on June 4, 1982, a former landfill employee told the Rhode Island Department of Health (RIDOH) he had been responsible for overseeing the disposal of drummed chemical wastes at the Truk-Away Landfill in the 1970s and that "hundreds of drums" had been disposed of at the landfill [15]. According to the former employee, the types of wastes disposed of at the landfill included: sulfur monochloride, benzyl chloride, xylol, toluene, pyridine, spent solvents, nitrobenzene, chlorobenzene, trichloroethylene (TCE), dyes, pigments, intermediate compounds made from benzene reactions, phenols, hydrogen peroxide, and benzene sulfonyl chloride [15].

The only known potential source of contamination on the property is the 36-acre landfill itself. There are no containment factors associated with this source as it is unlined, and its waste is uncovered [3,10]. More information regarding the quantity and specific types of waste disposed of at the landfill from 1970 to 1977 are unknown [2,21,31,56].

According to a Notification of Hazardous Waste Site form completed by Recycling Industries Inc. of Braintree, Massachusetts, approximately 432 cubic feet and 39,050 gallons of "low hazard material (i.e., paint waste, still bottoms, hydroxide sludge, non-hazardous wastes)" were disposed of at the Truk-Away Landfill from 1977 to 1978 (although the landfill had reportedly ceased operating in 1977). The source of the wastes were identified as paper/printing, chemical, plating/polishing, utility, and metal fabrication companies [4].

The facility began its operations in the elevated northwest section of the property in May 1970. Prior to February 19, 1971, the facility began dumping into the "swampy area" without first placing any clean material as required by the RIDOH, Division of Solid Waste Management. Samples collected from Buckeye Brook on February 19, 1971 by RIDOH reportedly revealed characteristics similar to samples collected at other landfills having water pollution problems [25].

An old oil disposal pit located off the eastern boundary of the property was identified as a possible source of unidentified water quality contamination in a letter from the state to Sanitary Waste Disposal of Rhode Island dated July 22, 1974 [39]. The exact location of this pit was not determined; however, during the 1993 CDM reconnaissance (recon), an oily area was observed near the former building location near the western boundary of the landfill (see Figure 2: Site Sketch) [2].

During its operation, the landfill was the subject of several complaints. In 1974 and 1975, the RIDOH was informed of a roach problem at the landfill, and the Warwick Department of Public Works sprayed the landfill with chlordane [27]. In April 1976, the RIDOH received several odor complaints regarding the Truk-Away Landfill. Inspections conducted by the department indicated that the odors were emanating from an area of the landfill approximately 75 feet by 45 feet in size and that the odors were associated with decaying organic matter. Truk-Away of Rhode Island, Inc. was halted from further filling of the area by the Rhode Island Department of Natural Resources [6,26]. In October 1976, the Town of Warwick's Councilman informed the State Division of Water Pollution Control that he had received several odor complaints from the landfill. A follow-up inspection noted odors emanating from restaurant refuse on the central area of the landfill (12).

In January 1976, Truk-Away of Rhode Island, Inc. applied for permission to alter freshwater wetlands by filling a portion of an unnamed swamp in order to extend its existing landfill operation approximately 460 feet southward. Permission was denied because of the landfill's proximity to freshwater wetlands and the potential impact on the Buckeye Brook, Warwick Pond, and Narragansett Bay wetlands [22]. On February 25, 1976, the Warwick City Council requested that RIDOH inspect the landfill twice per week to ensure compliance with regulations due to numerous public complaints regarding the site [62].

In 1977, State inspections and field investigations observed several daily cover and wind-blown refuse control violations at the Truk-Away Landfill, and a hearing was held in April 1977 before the Adjudication Hearing Officer [41]. The results of the hearing were not determined during file reviews.

RIDOT reportedly condemned and closed the landfill in 1977 because birds circling the site interfered with air traffic at the nearby airport [14]. In October 1977, RIDOT took ownership of the property [3]. At that time, RIDEM informed DOT of the closure requirements associated with sanitary landfills and suggested that the responsibility for closure be left with Truk-Away of Rhode Island, Inc. prior to the transfer of property ownership [38]. According to the previous owner and operator of the landfill, Charles Wilson, the landfill was not clean closed; only exposed waste was covered with 2 to 3 feet of fill [2]. In 1980, RIDEM informed RIDOT of its responsibility to adequately close the facility [38].

In October and December 1980 and February 1981, Rhode Island Division of Water Resources collected surface water samples at three surface water locations associated with the site: Brush Neck Cove, Little Pond, and Buckeye Brook at Warwick Avenue. Brush Neck Cove is located

approximately 0.9 mile southeast; Little Pond is located approximately 0.75 mile southeast of the landfill. Samples were analyzed for metals and volatile organics [59,15] (see Figure 1: Location Map). Analytical results indicated the presence of TCE (at 1 microgram per liter (μg/L)) and mercury (at 0.0014 milligram per liter (mg/L)) [32]. (See Surface Water Pathway.)

The site was entered into the CERCLA Information System (CERCLIS) on June 1, 1981. On April 19, 1982, a perimeter survey was conducted by Ecology and Environment, Inc. (E&E) as part of a Superfund Preliminary Assessment of the site. Observations noted during the perimeter survey included noticeable odors and a leachate plume on the western boundary of the site and trash blown outside the western perimeter [10].

On July 23, 1982, as part of a Superfund Site Inspection, E&E collected headspace samples with an organic vapor analyzer (OVA) of leachate from the landfill. A gas chromatograph identified toluene in the leachate west #2 sample at 2 parts per million (ppm) and tetrachloroethylene (PCE) in the leachate S.E. sample at 2 ppm [23]. An HNu, used to monitor air during E&E's sampling, detected 50 to 150 ppm total volatile organics at the western and eastern edges of the landfill [23].

In August 1987, RIDEM collected two samples, one sediment sample and one surface water sample, at the base of an unnamed pond on the northern boundary of the site. Analytical results indicated polychlorinated biphenyls (PCBs) (at 3 ppm) in the surface water sample and chloroethane (at 17 parts per billion (ppb)), methylene chloride (at 5 ppb), and TCE (at 1 ppb) in the sediment sample [31].

In December 1988, RIDEM wrote the Division of Airports to clarify that it was the responsibility of the RIDOT to prepare a closure plan for the landfill, employ a registered professional engineer to prepare plans and specification of the existing and final grades for the landfill, maintain a total thickness of 24 inches of cover material on all surfaces and faces, and provide the landfill with a drainage system to minimize surface water runoff onto and into the fill, to prevent erosion of the fill, to drain off rainwater falling on the fill, and to prevent the collection of standing water [18].

In 1988, medical waste was discovered at the landfill by a nearby worker. RIDOT reportedly covered the exposed waste with 8 inches of cover [2,18]. According to a letter from RIDEM to the Division of Airports, the landfill was being used to illegally dispose of solid waste in December 1990. At that time, access was not restricted and the cover material on the landfill was insufficient [1].

On March 1, 1991, the RIDEM investigated the property due to noxious odors offending workers at the FAA Control Tower. A "foul smelling odor" detected in the swampy area behind the tower was followed back to Buckeye Brook. The observed leachate from the landfill into Buckeye Brook was believed to be causing eutrophication in the brook. "A reddish bacteria was observed coming from a shiny blanket on the bottom of the brook. Gas bubbles were seen being released from the stream" [16].

RIDEM Division of Groundwater and Freshwater Wetlands identified that freshwater wetlands are present on or adjacent to the landfill and conditionally approved an "insignificant" alteration of the freshwater wetland as proposed in the Final Closure Plan dated March 1, 1991 [52].

The Division of Airports filed a Wetlands Determination Application with the RIDEM Division of Water Resources and submitted a closure plan to the RIDEM Air and Hazardous Materials Division on April 16, 1991 [62]. As part of its closure plan, RIDOT proposed the following material as cover for the landfill: asbestos-contaminated building demolition debris from the Providence Housing Authority, unclassified excavation from a runway rehabilitation project onsite gravel bank, previously petroleum-contaminated soil processed in Warwick until clean, West Warwick Sewage Treatment Plant composted sludge and odorless organic material, and dewatered Narragansett Bay dredged material [3]. On May 1, 1991, RIDEM conditionally approved the plan and asked for a schedule of closure activities within ten days [17]. In May 1991, the City of Warwick hired its own consultant (Environmental Resource Associates Engineering, Inc.) to review the wetlands application and closure application [3,19]. On May 8, 1991, the City of Warwick petitioned for Declaratory Rulings and requested a Contested Hearing regarding the landfill [3].

In a letter dated May 21, 1991, the Division of Airports postponed submittal of a closure schedule due to lack of the requested wetlands determination and the City of Warwick's objections to the closure plan [41]. On June 7, 1991, the City of Warwick appealed the ruling of the RIDEM Division of Groundwater and Freshwater Wetlands dated May 31, 1991 based on incompleteness and nonconformance with applicable law and regulation requirements [28].

On February 3, 1993, RIDEM sent a letter to the Division of Airports requiring the submittal of a schedule within ten days indicating the beginning and ending dates for closure of the landfill. According to the letter, RIDEM had not received any correspondence from the Division of Airports indicating the beginning and ending of all closure activities [19]. As of April 1993, RIDEM had received no correspondence from the Division of Airports regarding the landfill's closure. RIDEM sent another letter to RIDOT requiring a schedule of closure activities by April 30, 1993 [9].

As part of the Superfund SIP, CDM conducted an onsite recon of the landfill on March 10, 1993 [2].

WASTE/SOURCE SAMPLING

On May 11, 1993, CDM collected four soil samples and four leachate (soil) samples from potential source areas on the landfill including an oily area, an area containing mercury film packs, an area reportedly used for fly ash disposal, and leachate outbreaks identified by stained soil. (See Figure 3: Sampling Locations.) Reference samples were taken off the landfill from areas presumed not to have been affected by landfill activities. Figure 3 illustrates the approximate location of samples collected by CDM on May 11, 1993. Table 1 presents a summary of potential source samples collected by CDM on May 11, 1993. All samples were submitted for full organic, total metals and cyanide analysis through the EPA Contract Laboratory Program (CLP).

Table 2 and Table 3 are a summary of compounds and analytes detected through the CLP analysis of CDM soil and sediment samples. For each sample location, a compound or analyte is listed if it is detected at three times or greater than the reference sample concentration. Compounds or analytes which occur at a concentration three times or greater than the reference concentration (sample location SS-05) are designated by their approximate relative concentration above the reference value. If the analyte or compound is not detected in the reference sample, the sample quantitation limit (SQL) (for organic analyses) or sample detection limit (SDL) (for inorganic analyses) is used as a reference value. Accordingly, compounds or analyte are listed by their approximate concentration above the SQL or SDL only if they occur at a value equal to or greater than the reference sample's SQL or SDL.

The complete analytical results of the CDM sampling activities, including quantitation and detection limits are presented in Attachment A. Sample results qualified with a "J" on the analytical tables are considered approximate because of limitations identified during the CLP data validation. In addition, organic sample results reported at concentrations below quantitation limits, and confirmed by mass spectrometry, are also qualified by a "J" and considered approximate. All samples met data quality objectives as stated in the Task Work Plan dated April 1993.

Analytical results indicated the presence of several contaminants at levels exceeding three times the reference sample, including volatile organics, semivolatile organics, pesticides, PCBs, and several metals. A composite sample collected in the mercury film pack area (SS-01) indicated the presence of pyrene (520 ppb), PCB aroclor-1254 (at 660 ppb), benzo(b)fluoranthene (at 520 ppb), chromium (at 35 ppm), copper (at 34.2 ppm), mercury (at 22.6J ppm), nickel (at 91.3 ppm), and zinc (at 92.6 ppm). A sample collected from a suspected fly ash disposal area indicated the presence of toluene (at 880J ppb), bis(2-ethylhexyl) phthalate (at 7,200J ppb), barium (at 51.7 ppm), lead (at 122 ppm), and zinc (at 84.5 ppm). A sample collected from an oil stained area indicated the presence of benzo(b)fluoranthene (at 1,400J ppb), fluoranthene (at 520J ppb), pyrene (at 640 ppb), indeno(1,2,3-cd)pyrene (at 490J ppb), benzo(g,h,i)perylene (at 400 ppb), 4,4″-DDE (at 7.9J ppb), and PCB aroclor-1254 (at 110 ppb). Samples collected from three areas of leachate-stained soil indicated the presence of bis(2-ethylhexyl)phthalate (6,500J), di-n-octyl phthalate (at 1,600 ppb), toluene (at 19 ppb), PCB aroclor-1248 (at 36J ppb), 1,1-

[54]

GROUNDWATER PATHWAY

Truk-Away Landfill is located in the Seaboard Lowland section of the New England physiographic province. Geologic units north of Greenwich Bay consist of unconsolidated outwash deposits. The outwash body underlies an area of about 20 square miles that extends from Greenwich Bay on the south into the Providence quadrangle on the north and from the Providence River on the east to the upland on the west. The ice-contact deposits in the area are highly variable in lithologic character and consist of materials ranging from pebble, cobble, and boulder gravel to sand and minor amounts of silt. The groundwater north of Greenwich Bay is largely unconfined, and many of the ponds and streams are possibly surface outcrops of the water table. The groundwater moves generally west toward the Pawtucket and Providence Rivers or toward Greenwich Bay. Some water moves toward and discharges into the smaller brooks [35]. (See Figure 4: 4-Mile Radius.)

Surficial geology in the area is made up of outwash, medium to coarse grained sand and gravel interbedded with fine sand, silt, and clay; unconsolidated; generally well sorted and stratified. Bedrock at the landfill is made up of consolidated igneous, metamorphic and sedimentary rocks and is set approximately 70 feet below the surface [56]. Depth of groundwater ranges from 3 to 17 feet according to observations made in 1976 at seven test pits located at the landfill [36]. Drainage is in an easterly direction toward Buckeye Brook [56].

Groundwater beneath the landfill is classified by RIDEM as GB: groundwater sources which may not be suitable for public or private drinking water without treatment due to known or presumed degradation. The landfill is located approximately 1.25 miles west of groundwater classified as GA: groundwater sources which may be suitable for public or private drinking water sources [34,47]. There are no community drinking water wells and no wellhead protection areas located within 4 miles of the landfill. The Warwick Water Department supplies 26,000 active services (households) in Warwick with drinking water from the Scituate Reservoir. Kent County Water Authority supplies 24,000 service connections in Warwick with drinking water from the Scituate Reservoir and from groundwater. Kent County's drinking water supply wells are located in Coventry and East Greenwich [45,48,49]. There are no public groundwater supply sources within 4 miles of the Truk-Away Landfill. The nearest public drinking water well is located approximately 6 miles south of the property on the border of East Greenwich and North Kingston at the Hope River [45].

There are no records of private drinking water wells for the Warwick area. The Warwick Water Department indicated possible locations where groundwater may be used for drinking water. These areas include one residence on Payton Avenue (located approximately 2.25 miles east of the landfill), a private compound including five potential drinking water wells on Budlong Road (located approximately 2.3 miles northwest of the property), and five residences or businesses located on Bald Hill Road (located approximately 3.5 miles west of the property) [36]. The average number of persons per household in Warwick is 2.52 [51]. No groundwater samples were collected by CDM as part of this SIP.

TOTAL	28	0	28

[49]

SURFACE WATER PATHWAY

Drainage from the northwest section of the landfill flows overland north to a ponded section of Buckeye Brook which traverses the northern border of the property. In addition, groundwater appears to seep into this unnamed pond near the overland flow probable point of entry to the brook [2]. Wetlands surround the landfill to the north, east, and south and appear to drain toward Buckeye Brook. Several areas of the landfill itself are ponded and support wetland type plants, such as cattails and phragmites. Dark red and orange-stained soils, evidence of several leachate outbreaks, lead from the landfill's edges into the surrounding wetlands [2].

The 15-mile downstream surface water pathway includes Buckeye Brook, which travels east approximately 2.25 miles before its confluence with Old Mill Creek. Old Mill Creek then continues approximately 1 mile before entering Narragansett Bay. The remainder of the 15-mile pathway includes an 11.75-mile radial arc of Narragansett Bay [61,63].

The landfill is in a low lying area classified as a Mineral Swamp by the Rhode Island Department of Natural Resources [56]. On August 20, 1974, the Rhode Island Department of Natural Resources determined that an area immediately south of the landfill is a swamp of over 3 acres and is subject to the provisions of the Freshwater Wetlands Act [24]. On May 31, 1991, the RIDEM Division of Groundwater and Freshwater Wetlands determined that freshwater wetlands are present at the Truk-Away Landfill. An emergent community was identified adjacent to the roadway [52]. In addition, according to a 1973 National Wetlands Inventory Map, the following wetlands are located within the boundaries of the landfill: Palustrine, forested, broad-leaved deciduous; Palustrine emergent, and Palustrine open water. Palustrine scrub/shrub, broad-leaved deciduous and Palustrine, forested, broad-leaved deciduous wetlands are located along Buckeye Brook downstream of the probable point of entry [57].

In 1976, the Rhode Island Department of Natural Resources described the swamp located on the landfill as an important "refuge for what wildlife remains in the area. Elimination of this habitat will have a significant negative impact on local wildlife populations." The swamp is a part of Buckeye Brook and the Warwick Pond ecosystem which supports a major anadromous fish (alewife) run and forms an integral part of the Narragansett Bay ecosystem [22]. According to a 1974 letter from the RIDOH, herring make a spring run to Warwick Pond via Buckeye Brook [25]. Warwick Pond is located approximately 0.4 mile northeast of the probable point of entry [60].

Buckeye Brook is classified as a Class B waterway by RIDEM [56]. Class B includes the following water uses: public water supply with appropriate treatment, agricultural uses, bathing and other primary recreational activities, and fish and wildlife habitat [64]. The fresh/salt water boundary in Buckeye Brook is located at the West Shore Road bridge [33]. Old Mill Creek is a tidalwater and likely supports similar fish to the coastal waters of Narragansett Bay. Narragansett Bay supports flounder as well as shellfish [50]. Approximately 17,826,000 pounds of shellfish were caught in 1991 [33,44,50].

The State has designated two wildlife management areas in Narragansett Bay within the 15-mile downstream surface water pathway. Prudence Island Management Area is located 8.25 miles south of Old Mill Creek, and North Patience Island Management Area is located 7.75 miles south [60,61]. Both Prudence and North Patience Island Management Areas are considered critical habitats for species of special concern as well as Hog Island (located 6.25 miles from the mouth of Old Mill Creek) and Mill Gut (located just north of Colt State Park), approximately 3.8 miles from the mouth of Old Mill Creek [58,61].

TABLE 5

Water Bodies Within the Surface Water Segment of Truk-Away Landfill

Surface Water Body	Descriptor[a]	Length of Reach	Flow Characteristics (cfs)[b]	Length of Wetlands
Buckeye Brook	Minimal Stream	2.25 miles	< 10	0.75 mile
Old Mill Creek	Coastal Tidal Waters	1 mile	> 100	NA
Narragansett Bay	Deep Ocean Zone	11.75 miles	> 100	NA

[a] Minimal stream. Small to moderate stream. Moderate to large stream. Large stream to river. Very large river. Coastal tidal waters. Shallow ocean zone or Great Lake. Deep ocean zone or Great Lake. Three-mile mixing zone in quiet flowing river.
[b] Cubic feet per second.
[60,61]

In 1980, the RIDEM Division of Water Resources established a sampling program in the area of the Truk-Away Landfill which consisted of three stations located on Buckeye Brook at Warwick Avenue, Little Pond, and Brush Neck Cove at the western end of Canfield Avenue. Samples were collected three times during a five month period (October and December 1980 and February 1981) and were analyzed for heavy metals, trihalomethanes, aromatic solvents, halogenated volatiles, and total and fecal coliform. Results as of April 1981 indicated no concentrations above EPA Water Quality Criteria for drinking water. TCE was the only organic compound detected at 1 μg/L. Mercury was detected at 0.0014 mg/L, slightly above the recommended criteria for freshwater aquatic life. According to RIDEM's report, the bacteriological sample results indicated levels compatible with an urbanized drainage area [32].

On May 11, 1993, CDM collected seven sediment samples. Three samples were collected upstream of the property from areas presumed to be undisturbed by the landfill's operations. SD-06, collected immediately upstream of the landfill was used as the reference sample for Table 7 and Table 8. Figure 3 illustrates the approximate location of samples collected by CDM. Table 6 presents a summary of the surface water pathway samples collected by CDM. All samples were submitted for full organic, total metals, and cyanide analysis through CLP.

CDM was not able to collect a sample from Buckeye Brook downstream of the landfill due to lack of remaining daylight. This sample location, SD-05, is located off Rufus Road in Warwick, east of the landfill [2].

Table 7 and Table 8 are a summary of compounds and analyte detected through the CLP analysis of CDM sediment samples. For each sample location, a compound or element is listed if it is detected at three times or greater than the reference sample concentration. Compounds or elements which occur at a concentration three times or greater than the reference concentration (sample location SD-06) are designated by their approximate relative concentration above the reference value. If the element or compound is not detected in the reference sample, the SQL (for organic analyses) or SDL (for inorganic analyses) is used as a reference value. Accordingly, compounds or analytes are listed by their approximately concentration above the SQL or SDL only if they occur at a value equal to or greater than the reference sample's SQL or SDL.

The complete analytical results of the CDM sampling activities, including quantitation and detection limits are presented in Attachment A. Sample results qualified with a "J" on the analytical tables are considered approximate because of limitations identified during the CLP data validation. In addition, organic sample results reported at concentrations below quantitation limit and confirmed by mass spectrometry, are also qualified by a "J" and considered approximate.

TABLE 6

	Iron	16,100 J	5,140 J	3.1 x REF
	Lead	75.6	5	15.1 x REF
	Mercury	0.31 J	0.06 J	5.2 x REF
	Potassium	1,090 J	275 UJ	4.0 x REF
	Zinc	142	45.1	3.1 x REF

REF = Reference concentration.
J = Quantitation is approximate due to limitations identified during the quality control review.
mg/kg = Milligrams per kilogram (parts per million).
[54]

SOIL EXPOSURE PATHWAY

Entrance to the landfill is barred by a Jersey barrier; the landfill's perimeter is surrounded by an 8-foot chain-link fence topped with barbed wire. During the recon, CDM observed an approximately 25-foot section of fence that had been cut leaving a wide open space where worn paths indicated recreational dirt biking onsite. Well worn dirt trails lead an estimated 0.1 mile from the end of Bartlett Drive to the fence opening. The only workers within 200 feet of potential contamination are those working in the office park located at the former Leesona Corporation. Distance from the office park building to the landfill's western boundary is estimated at 100 feet [29,60]. The nearest offsite residence is located approximately 500 feet south of the landfill [13,29,59]. There are an estimated 701 people living within 1 mile of the landfill [13]. There are no schools or day-care centers within 200 feet of the landfill [2]. There are no terrestrial sensitive environments on the landfill [21].

During the recon, CDM observed exposed waste on the landfill including: medical waste, mercury film packs, paint cans, fly ash, household trash, and electrical waste [2]. CDM collected surface soil samples from the landfill and sediment samples from the unnamed pond and wetlands. Analytical results are in the Waste/Source Sampling section of this report and are summarized in Tables 2 and 3.

In eight surface soil samples collected from within 6 inches of the ground surface and in areas of prior waste disposal and leachate outbreaks, the maximum VOC contaminant detected was toluene at 880J ppb. The highest concentration of a semivolatile compound was bis(2-ethylhexyl)phthalate at 7,200J ppb. 4,4'-DDE, at 7.9J ppb, was the only pesticide detected onsite. PCB aroclor-1254 was detected at 110 ppb, the highest concentration of PCBs detected onsite. Of the inorganics, copper was detected at a maximum of 34.2 ppm, lead at a maximum of 122 ppm, mercury at a maximum of 22.6J ppm, nickel at a maximum of 91.3 ppm, silver at 5.5 ppm, zinc at 394 ppm, barium at a maximum of 104 ppm, and iron at a maximum of 97,500J ppm. Although many of these contaminants were detected in the reference sample taken off the landfill property the, above-mentioned contaminants were detected from 3 to 376 times greater than the reference concentrations (see Tables 2 and 3 and Figure 3) [54,55].

A larger number of volatile and semivolatile organics were detected in four sediment samples collected on the landfill property within 6 inches of the ground surface. The highest concentration of VOCs detected was chloroethane at 95 ppb. The highest concentration of semivolatile organic compounds was pyrene detected at 10,000J ppb. PCB aroclor-1260 was detected at a maximum of 140J ppb, and 4,4'-DDE was detected at 5.8 ppb. In the sediment samples, barium was detected at 116 ppm, calcium at 3,270 ppm, copper at 55.7 ppm, iron at 67,800J ppm, lead at 106 ppm, mercury at 0.31J ppm, potassium at 1,150J ppm, and zinc at 189 ppm. Bis(2-ethylhexyl)phthalate was the only organic contaminant detected in the reference sediment sample collected upstream of the landfill property. Although several inorganics were detected in the reference sample, the above-mentioned inorganic contaminants were detected in downstream sediment samples at concentrations from 3 to 21.2 times greater than the reference samples [54,55].

AIR PATHWAY

The nearest individuals to onsite source areas are workers in the office park located at the former Leesona Corporation. Distance from the building to the landfill's western boundary is estimated at 100 feet [29,59]. The nearest residents are located south of the property, approximately 500 feet from the landfill [13,29,59]. There are an estimated 701 people living within 1 mile of the landfill and an estimated 29,704 people living within 4 miles of the property by radial distance ring [13]. Worker population within 4 miles of the property includes: 230 employees at Jay Printing facility (Industrial Drive) and employees working in the office park located at the former Leesona Corporation [3,48]. The nearest school is the Lippitt School located in Warwick, approximately 0.5 mile south of the landfill. Approximately 383 students are enrolled at this school [43]. There are 240 students enrolled at Buttonwoods School located approximately 1 mile south of the landfill [42]. (See Table 9: Estimated Population Within 4 Miles of Truk-Away Landfill. Note: this table includes residents as well as students and workers identified above.)

TABLE 9

Estimated Population Within 4 Miles of Truk-Away Landfill

Radial Distance from Truk-Away Landfill (miles)	Estimated Population
0.00 - 0.25	37
>0.25 - 0.50	689
>0.50 - 1.00	848
>1.00 - 2.00	3,189
>2.00 - 3.00	6,450
>3.00 - 4.00	18,734
TOTAL	29,947

[13,42,43]

In July 1982, E&E used an HNu to monitor organics in air during leachate sampling. The HNu detected 50 to 150 ppm in air at leachate seeps on the western and eastern edges of the landfill [23]. CDM used an organic vapor monitor (OVM) to monitor ambient air during the March 1993 recon and May 1993 sampling event. No concentrations above background were detected [2].

The nearest sensitive environment to the landfill are the wetlands located along the northern, eastern, and southern boundaries of the property. Based on a 1976 plan of the property, at least 16 acres of wetlands surround the landfill [29].

SUMMARY AND CONCLUSIONS

The Truk-Away Landfill is located on Industrial Drive in Warwick, Rhode Island. The landfill accepted municipal and industrial wastes during its operations from 1970 to 1977. According to a landfill employee, hundreds of drums containing sulfur monochloride, benzyl chloride, xylol, toluene, pyridine, spent solvents, nitrobenzene, chlorobenzene, trichloroethylene, dyes, pigments, intermediate compounds made from benzene reactions, phenols, hydrogen peroxide, and benzene sulfonyl chloride were disposed of at this landfill.

During its operation, the landfill was the subject of several complaints, including roach and odor problems. In 1977, the landfill was sold to the Rhode Island Department of Transportation, Division of Airports and ceased operations due to the hazards posed to the nearby T.F. Green State Airport by sea gulls attracted to the landfill. The landfill has never been clean closed. Various types of waste are exposed throughout the landfill including medical waste, electrical waste, paint cans, mercury film packs, and fly ash. The landfill is accessible due to an opening in the fence. Dirt bike trails were noted during the 1993 CDM site reconnaissance.

There are no public or known private drinking water wells within a 4-mile radius of the landfill; although it is possible that there are groundwater wells serving private residences 2 to 3 miles from the landfill. Surface water from the landfill drains to Buckeye Brook. The probable point of entry (PPE) of surface water runoff to a perennially wet surface water body is at Buckeye Brook located on the northern boundary of the property. From the PPE, surface water flows east approximately 2.25 miles downstream before discharging to Old Mill Creek. Surface water continues to flow east approximately 1 mile before discharging into Narragansett Bay. Sensitive environments along the 15-mile downstream surface water pathway include Patience Island Management Area and North Prudence Island Management Area.

The nearest residence is located approximately 500 feet south of the landfill. There are no people living on or within 200 feet of an area of observed contamination. An estimated 701 people live within 1 mile of the landfill. Analytical results from surficial soil samples collected by CDM showed chromium, lead, mercury, polychlorinated biphenyls, toluene, and several semivolatile organic compounds to be present on the landfill.

The nearest individual to the landfill are workers at the office park located approximately 100 feet west of the landfill. There are an estimated 29,947 people who live, work, or attend school within 4 miles of the landfill. Sensitive environments within 4 miles of the landfill are wetlands associated with Buckeye Brook.

ATTACHMENT A

TRUK-AWAY LANDFILL
SOIL AND SEDIMENT SAMPLE ANALYTICAL RESULTS
CDM SAMPLES COLLECTED MAY 11, 1993

Data Summary Key

A - Acceptable data.

J - The associated numerical value is an estimated quantity.

U - The compound was analyzed for but was not detected. The associated numerical value is the sample quantitation limit.

UJ - The compound was analyzed for, but was not detected. The sample quantitation limit is an estimated quantity.

R - Reject data because quality control criteria were exceeded. The data are unusable (compound may or may not be present). Resampling and reanalysis is necessary for verification.

List of Organic Data Validation Acronyms

BNA	-	base/neutral/acids (also referred to as semivolatiles)
CAS	-	Chemical Abstracts Service
CC	-	continuing calibration
CRQL	-	contract required quantitation limit
CSF	-	Complete Sample Delivery Group File
CLP	-	Contract Laboratory Program
%D	-	percent difference
4,4'-DDD	-	dichlorodiphenyldichloroethane
4,4'-DDE	-	dichlorodiphenyldichloroethylene
4,4'-DDT	-	dichlorodiphenyltrichloroethane
DQO	-	Data Quality Objective form
EPA	-	Environmental Protection Agency
BHC	-	benzene hexachloride (alpha, beta, delta, gamma)
GC/MS	-	gas chromatography/mass spectrometry
GPC	-	gel permeation chromatography
IC	-	initial calibration
ID	-	identification number
IS	-	internal standard
ORDA	-	Organic Regional Data Assessment form
PCB	-	polychlorinated biphenyl
QC	-	quality control
RAS	-	Routine Analytical Services
RIC	-	reconstructed total ion chromatogram
RPD	-	relative percent difference
RSD	-	relative standard deviation
RT	-	retention time
SDG	-	Sample Delivery Group
SOW	-	Statement of Work for Organic Analysis
SV	-	semivolatile organic compounds
TCL	-	target compound list
TIC	-	tentatively identified compound
TR#	-	Traffic Report number
TR# DL	-	sample analyzed at a secondary dilution
TR# MS	-	matrix spike sample
TR# MSD	-	matrix spike duplicate sample
TR# RE	-	re-analyzed sample
ug/L	-	microgram per liter
ug/Kg	-	microgram per kilogram
VOA	-	volatile organic analysis
VOC	-	volatile organic compound

Sample quantitation limits are reported on dry weight basis.
U - The compound was considered not detected due to blank contamination. The associated numerical value is the sample quantitation li
UJ - The compound was not detected. The sample quantitation limit is an estimated value.
R - The datum was rejected.

R - The datum was rejected.

List of Inorganic Data Validation Acronyms

AA	-	atomic absorption spectrophotometry (flame or graphite furnace)
CRDL	-	contract required detection limit
2xCRDL	-	2 times the contract required detection limit
3xCRDL	-	3 times the contract required detection limit
CCB	-	continuing calibration blank
CCV	-	continuing calibration verification
CLP	-	Contract Laboratory Program
CSF	-	Complete Sample Delivery Group File
CV	-	manual cold vapor atomic absorption spectrophotometry
DQO	-	Data Quality Objective form
EPA	-	Environmental Protection Agency
ICB	-	initial calibration blank
ICP	-	inductively coupled plasma emission spectrophotometry
ICS	-	interference check sample (A - mix A, AB - mix AB)
ICV	-	initial calibration verification
IDL	-	instrument detection limit
2xIDL	-	2 times the instrument detection limit
IRDA	-	Inorganic Regional Data Assessment form
LCS	-	laboratory control sample (W - aqueous, S - solid)
mg/L	-	milligram per liter
mg/Kg	-	milligram per kilogram
MSA	-	method of standard addition
PB	-	preparation blank (W - aqueous, S - soil/sediment)
QC	-	quality control
RAS	-	Routine Analytical Services
RPD	-	relative percent difference
RSD	-	relative standard deviation
SAS	-	Special Analytical Services
SDG	-	Sample Delivery Group
SOW	-	Statement of Work for Inorganic Analysis
TAL	-	target analyte list
TR#	-	Traffic Report number
TR# D	-	laboratory duplicate sample
TR# DA	-	laboratory duplicate spike sample
TR# DL	-	sample analyzed at a secondary dilution
TR# RE	-	re-extracted and reanalyzed sample
ug/L	-	microgram per liter

STATE OF RHODE ISLAND AND PROVIDENCE PLANTATIONS
Department of Environmental Management
Bureau of Environmental Protection
INTER-OFFICE MEMO

TO: Leo Hellested
Office of Waste Management

DATE: May 7, 1999

THROUGH: Michael Mulhare, Supervising Sanitary Engineer MJM
Office of Compliance and Inspection

FROM: John Leo, Sanitary Engineer JL
Office of Compliance and Inspection

SUBJECT: Mercury contamination at the former Truck-Away Landfill, end of Industrial Lane, Warwick, R.I.

On April 7, 1999 a brush fire swept across the former Truck Away Landfill. Because of the closeness to the airport, the Fire Department of Warwick and the State Airport Crash Crew responded.

On April 8, 1999, Jim Ball and I inspected the landfill and located a large amount of Polaroid battery packs on the surface of the landfill in the burned over area.

These packs were brought to R.I. by Truck Away from Polaroid of Massachusetts. This operation was overseen by John Quinn of the former solid Waste section of DOH.

Several of the thousand or so battery packs were taken as evidence and sent for analysis to Mitkem Laboratories on April 13, 1999 (copy of results attached).

Analysis shows that the battery packs are highly toxic waste with extractable levels of mercury at 2 ppm. This level is 10 times higher than the hazardous waste regulated level of .02 ppm mercury.

The current situation at the landfill is that the public and first responders can be exposed to highly toxic wastes.

It is my understanding that this project is being evaluated as a former solid waste landfill and will be managed by your group. I recommend immediate action be taken to remove the exposed mercury battery packs as hazardous waste. I also recommend that the site be characterized to determine the potential environmental and public health impacts from this landfill.

If you have any further questions, please feel fee to contact John Leo at extension 7127.

Subject: Limited Environmental Site Investigation Work Plan
T. F. Green Airport
Former Truk Away Landfill Site
Warwick, Rhode Island

Dear Ms. Grandchamp:

On behalf of the Rhode Island Airport Corporation (RIAC), Camp Dresser & McKee, Inc. (CDM) hereby submits the enclosed Limited Environmental Site Investigation Work Plan for the former Truk Away Landfill Site at the T. F. Green Airport in Warwick, Rhode Island. CDM requests that the Rhode Island Department of Environmental Management (RIDEM) review the attached document.

As we discussed at the July 20, 2000 meeting, RIAC and CDM would like to begin field work as soon as possible. Since some of the proposed work at the site will be within the 50 foot perimeter wetland, a phased approval process is an option that we would be interested in exploring. If this is the case and RIDEM anticipates a long review process for work within the wetland buffer zone, we would seek a separate approval for work outside of the wetland area.

CDM has investigated the use of ground penetrating radar (GPR) and electromagnetic geophysical (EM) equipment as part of this investigation. We believe that due to the possible presence of a wide variety of material being placed in the landfill, including many different types of metal material, the use of this equipment will likely produce a significant number of false positives when searching for possible buried drums. In addition, since the depth of landfill material may at depths of up to 30 feet, the ability of this equipment to identify possible buried drums at this depth is questionable. Therefore, at this time GPR will not be used as part of this investigation.

Please call either of the undersigned at (617) 452-6000 if you have any questions or if you need additional information.

Very truly yours,

CAMP DRESSER & McKEE INC.

Section 1
Introduction

Camp Dresser & McKee, Inc. (CDM) is currently under contract with the Rhode Island Airport Corporation (RIAC) to conduct a Limited Environmental Site Investigation at the former Truck Away Landfill at the T. F. Green Airport in Warwick, Rhode Island. Presently CDM is also under contract with RIAC to collect information on the wetlands and the subsurface conditions and geotechnical properties of the soils in the landfill area. Information gathered from these activities will be used in evaluating the feasibility of constructing cargo buildings, aprons and taxiways on the landfill area.

1.1 Purpose

CDM has developed this work plan for a limited environmental investigation of the landfill area for review by the Rhode Island Department of Environmental Management (RIDEM). The purpose of this work plan is to provide RIDEM with a detailed description of the planned activities at the site. This work plan will also serve as a guide for CDM field personnel overseeing the investigation.

1.2 Work Plan Objectives

This work plan details the specific objectives of this work, the data required to support these objectives and the general methods that will be used in performing the work. The scope detailed herein is not intended to include a comprehensive site investigation of the landfill area. CDM is performing this limited investigation now to take advantage of the subsurface explorations being conducted for geotechnical purposes, and to give RIAC, RIDEM, the Rhode Island Department of Transportation (RIDOT) and the Rhode Island Department of Administration (RIDOA) preliminary data concerning the potential impacts of landfill operations to soil, groundwater and/or soil gas in this area. More comprehensive investigations may be required to provide adequate information for landfill closure.

1.3 Background Information

RIAC is in the process of evaluating the feasibility of constructing up to four 30,000 square foot cargo buildings with concrete aprons and a taxiway on the landfill area at the T. F. Green Airport in Warwick, Rhode Island. The landfill area covers approximately 34 acres and is almost completely surrounded by wetlands. The landfill surface is vegetated with low growing shrubs and grasses and occasional stands of small trees with maximum height of approximately 20 feet. Ground surface over most of the central part of the landfill is relatively flat. The perimeter of the landfill is generally about 10 to 20 feet. lower than in the center. The slopes from the perimeter up to the central area are gradual (generally 5H:1V or flatter). The landfill area is bounded to the west by industrial property, to the north by wetlands and the south end of Runway 34-16, to the east by wetlands and a former City of Warwick

dump, and to the south by residential property. A site locus plan is provided on **Figure 1-1.**

Correspondence from Truk-Away and Sanitas Waste Disposal to the Division of Solid Waste Management during the 1970's suggests that the site is/was underlain by extensive deposits of peat. The peat was noted as being up to 30 ft. deep below the ground surface that existed at that time. Although the waste materials placed in the landfill are not well documented, reference is made to "rubbish and construction demolition debris." The removal of batteries from the landfill has occurred in the past. Historical news accounts indicate that oily water was disposed of in the landfill. CDM has not reviewed any other written documents that indicates hazardous materials have been disposed of in the landfill area, however.

In addition to the work outlined in this plan, a wetland delineation survey has been completed, and a topographic survey of the landfill, will be conducted at the site to locate borings, wells, soil gas probes and test pit locations and other relevant site features.

CDM Camp Dresser & McKee Inc.

Section 2
Field Investigations

This section outlines field investigations to be performed at the site to evaluate subsurface conditions. In particular, a description of soil boring, monitoring well installation, soil gas probe installation, test pit excavation and sampling of environmental media will be presented. As previously noted, the proposed investigation is limited in nature, and a more comprehensive subsurface investigations may be proposed pending the outcome of this initial study. Field investigations for the site will also evaluate the feasibility of constructing cargo buildings, aprons and taxiways at the site. Since this work plan will be used by field personnel, reference to geotechnical portions of the work have also been included.

2.1 Soil Borings Advancement

Up to 10 test borings will be advanced by a qualified subsurface exploration contractor. Six off these locations will be designated for completion as groundwater monitoring wells and collection of soil samples for chemical analysis. The borings will be advanced through the landfilled material and at least 30 ft. into the underlying naturally deposited inorganic soils, or to the top of bedrock, whichever occurs first. Standard split-spoon samples of soil will be collected in accordance with ASTM D1586 and CDM's applicable standard operating procedure (SOP's). CDM SOPs that are applicable to this project are included in Appendix A. Samples will be collected every five feet of depth or at changes in soil strata, beginning with the first sample at the ground surface to five feet below ground surface (bgs) interval. Separate soil samples will be collected for environmental and geotechnical purposes.

Environmental samples will be screened for the presence of volatile organic compounds (VOCs) through use of a photoionization detector (PID). At each of the six boring locations where monitoring wells will be installed, the soil sample with the highest PID reading will be laboratory analyzed for total petroleum hydrocarbons (TPH) by EPA Method 418.1, VOCs by EPA Method 8260, semi-volatile organic compounds (SVOCs) by EPA Method 8270, pesticides by EPA Method 8081, PCBs by EPA Method 8082, Total Organic Carbon (TOC) and TAL metals by EPA Method 200/6000/7000 series. Results of the environmental analyses will be included in the Limited Environmental Site Investigation Report.

Soil samples for geotechnical analyses will be collected from the naturally deposited soils only. The landfilled material will be observed and described on the test boring logs, however, geotechnical samples will not be collected. The CDM Geotechnical Laboratory in Cambridge, Massachusetts will conduct testing to aid in soil classification and the determination of the engineering properties of the soils below the landfilled material. Up to 10 grain size analyses and up to five Atterberg Limit determinations will be performed on the samples.

Auger cuttings, consisting of landfilled materials and native soils, will be brought to the landfill surface during the advancement of borings. CDM will direct the

subcontractor to segregate the waste materials from the clean soils. Test borings will be backfilled with cement-bentonite grout to an elevation no lower than the bottom of the landfilled material. Auger cuttings can be utilized to fill the borehole from the bottom of the landfilled material to the ground surface. The waste material will be replaced in the bore hole above the cement-bentonite grout elevation to the extent practical. Excess waste material will be drummed for off-site disposal if on site disposal is prohibited. CDM estimates that no more than 5 cubic yards of waste material will be generated for disposal.

Standard truck-mounted drill rigs can access the boring locations; there are no restrictions on drilling activities (height) related to the operation of the airport. Depths and locations of the borings, as well as sampling methods, will varied to meet the subsurface conditions encountered. The boring sites will be restored to as near to pre-drilling condition as is practicable and marked for future survey in the event that any locations have changed from previously surveyed staked locations.

A health and safety plan (HASP) will be developed for field activities described in this work plan. All drilling sampling and test pitting activities will be completed in Level D Personal Protective Equipment (PPE) unless breathing zone monitoring indicates work should be conducted in Level C PPE. CDM will monitor environmental conditions exposed during drilling to document that work in Level D PPE is appropriate or to determine that work should be suspended due to environmental conditions. Contingency Planning and Notification issues are discussed in Section 3.3.

2.2 Monitoring Well Installation

At six of the ten soil boring locations, CDM will complete the borings as overburden groundwater monitoring wells. Proposed monitoring well locations are shown on **Figure 2-1**. The monitoring wells will consist of Schedule 40 2-inch inside diameter (ID) polyvinyl chloride (PVC) well screen (10 feet long) with 0.02 inch slots installed seven feet below the observed groundwater table. A 2-inch ID schedule 40 PVC well riser will extend from the top of the well screen to the ground surface. Wells are to be installed and developed in accordance with applicable CDM SOPs, included in Appendix A and all wells will be completed with stick-up road boxes.

2.3 Groundwater Sampling

Two weeks after the wells have been developed, CDM will collect groundwater samples from each of the six newly installed monitoring wells. Groundwater sampling will be performed in accordance with CDM's Groundwater Sampling SOP, included in Appendix A. Purge waters will be handled in accordance with DEM Division of Site Remediation Policy Memo 95-01, Guidelines for the Management of Investigative Derived Wastes, included as Appendix C. Groundwater samples will be analyzed for the following parameters: Hazardous Substance List (HSL) VOCs according to EPA Method 8260, semi-volatile organic compounds (SVOCs) according to EPA Method 8270, TAL metals by EPA Method 200/6000/7000 series, nitrate

nitrogen, alkalinity, chemical oxygen demand, chlorides, total dissolved solids, total cyanide, sulfate, pesticides by EPA Method 8081, and PCBs by EPA Method 8082.

2.4 Soil Gas Probes

CDM will oversee two days of soil gas probe installations (approximately 15 locations) to assess the presence of landfill gas at the landfill. Appendix C continues the ASTM and CDM SOP's for soil gas monitoring. Portable gas monitoring equipment will be used to determine the concentrations of hydrogen sulfide, methane, carbon dioxide, oxygen and VOCs in shallow soil gas. Fifteen soil gas probe locations are shown on Figure 2-1.

A hand held portable hammer drill will be used to advance five foot long, 5/8-inch diameter hollow steel sampling probes into the ground. Each probe, equipped with a retractable sample point, will be driven to a depth of 3-4 feet below ground surface. After reaching the desired sample location, the probe will be extracted approximately 4 inches to sufficiently open the retractable sample tip and expose the 3 inch screened interval of the point.

The sample point will consist of a four inch length of ½ inch machined steel pipe with several 1/16 inch holes drilled through the horizontal plane. A stainless steel mesh jacket will cover the length of the sample point containing the 1/16 inch holes to prevent soil particles from entering the sample probe during sampling. Teflon tubing will be attached to the sample point and run up through the hollow probe, exiting through a special drive adapter.

The exiting end of the tubing will be attached to an electrical vacuum pump and approximately 100 - 200 probe volumes of soil gas will be purged through the probe. The dynamic purging of the soil gas probe serves to create a cone of influence encompassing soil void areas some distance, depending on soil type from the sample point, allowing for VOC determination from an extended subsurface volume. The discharge from the vacuum pump will be monitored continuously during the purging cycle with a PID, and the highest VOC concentration will be recorded. After purging, hydrogen, sulfide, methane carbon dioxide and oxygen will be measured with portable gas monitoring equipment

2.5 Test Pit Excavation

Approximately 22 test pits will be excavated around the periphery of the landfill to generally delineate the horizontal limit of the landfilled materials. Test pits will be excavated using a tracked or wheeled excavator capable of accessing all investigation locations. If waste is identified within a test pit, another test pit will be excavated 20 feet away in an attempt to locate the edge of waste. The test pits will be excavated to a maximum depth of 12 feet. After the test pitting is completed, CDM will prepare test pit logs which will provide a description of encountered materials, general strata changes, depth to groundwater and total excavation depth. The logs will note where

waste material was encountered. CDM will not collect soil samples for analysis under this activity.

It should be noted that CDM will be excavating test pits within the 50 perimeter zones of the wetlands and potentially the wetlands themselves. This information is necessary to evaluate whether landfilled material extends beneath the wetlands.

2.6 Wetland Delineation

Applied Bio-Systems Inc. of Kingston, Rhode Island and under subcontract to CDM will conduct field work to delineate the limit of ecological wetlands and document the limit of state and federal jurisdictional wetlands for seven wetland units in the vicinity of the landfill area. This information will be incorporated onto the topographic survey plans.

2.7 Site Survey

A site survey will be performed by a subcontractor. The site survey will be completed to collect the following information. The topography of the area will be developed. The topographical information will be suitable to develop 2 foot contours throughout the site area. The locations of above ground on-site facilities will be surveyed including buildings (if any), paved areas, roadways, fencing or any other distinguishing characteristics. The locations of staked soil borings, monitoring wells, soil gas probes, test pits, wetlands flags and property lines will be surveyed. The survey information will be provided by the subcontractor on a plan of suitable scale. This plan will form the base map for all future work.

2.8 Groundwater Flow Direction

CDM will measure the depth to groundwater in each of the available wells and will perform an elevation survey of well casings. The information collected will be used in conjunction with topographic survey data to develop a general overburden groundwater flow direction. A groundwater contour map will be included in the Limited Site Investigation report.

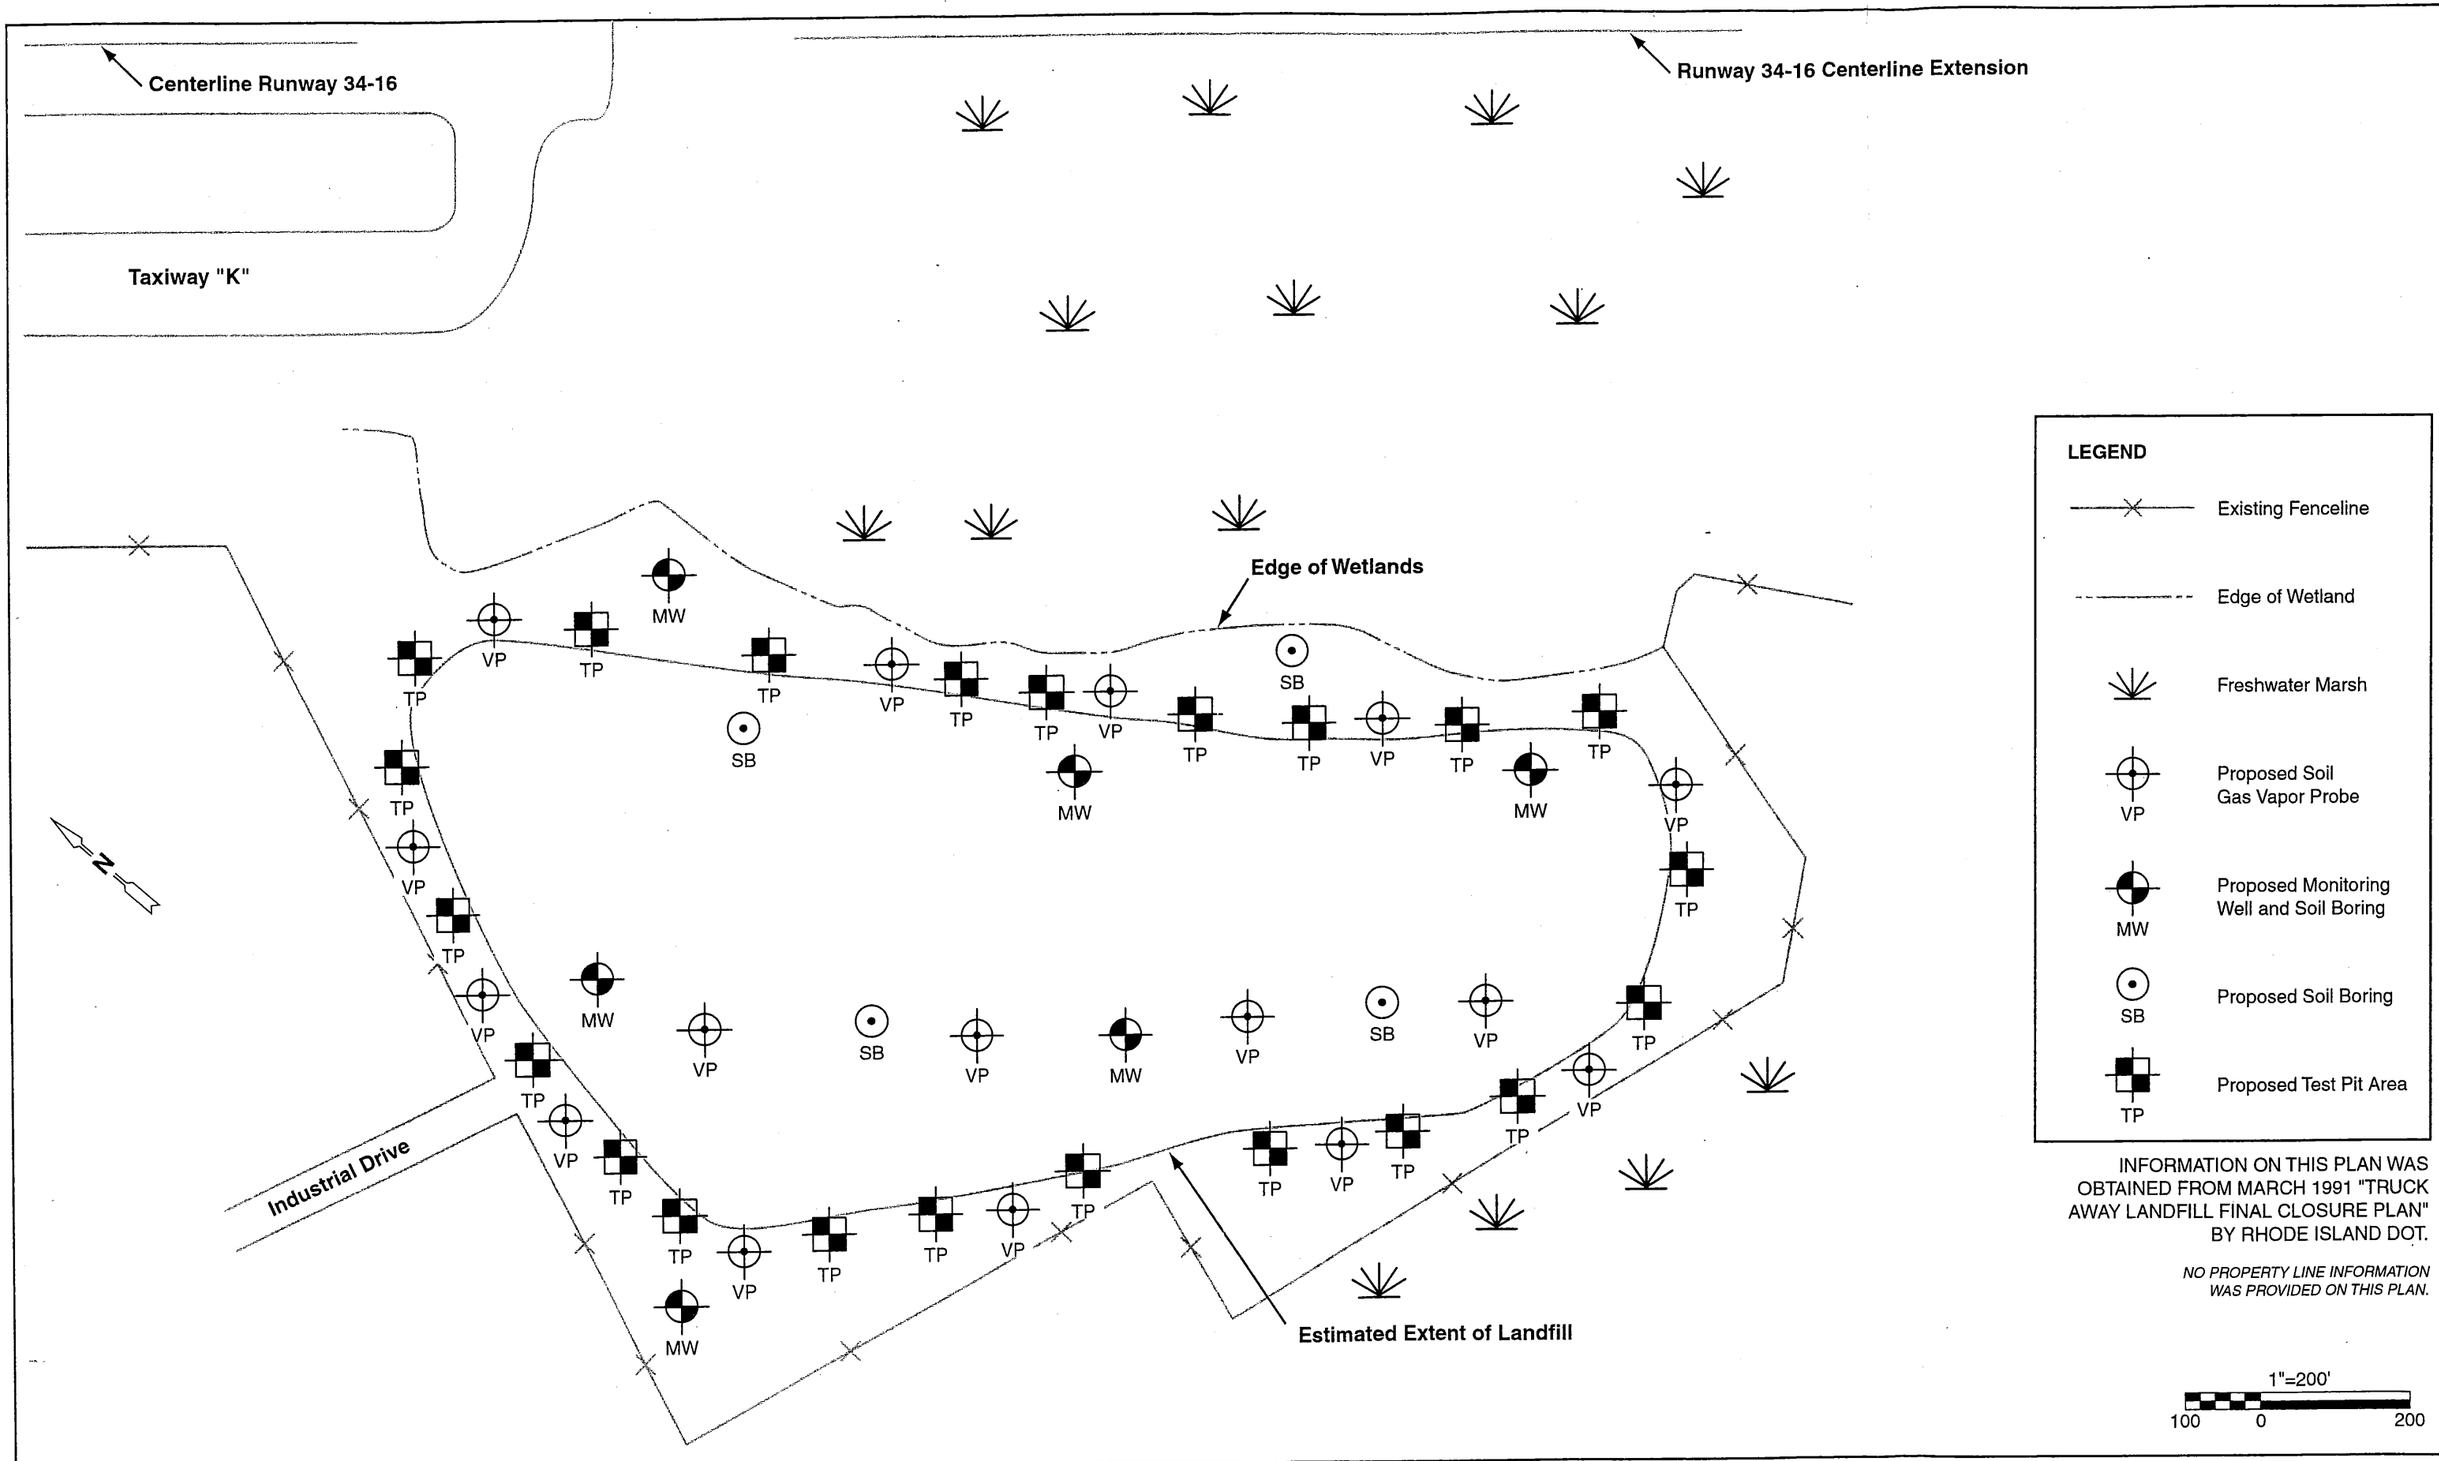

Figure 2-1
Proposed Sampling Locations

Work Plan Limited Site Investigation
Former Truck Away Landfill Site
Warwick, Rhode Island

CDM Camp Dresser & McKee Inc.

Section 3
Site Management Plan

This section presents a site management plan that addresses procedures to be employed by CDM and its subcontractors during investigation activities.

3.1 Site Access

CDM will obtain site access through RIAC, specifically for access to the former Truk-Away Landfill area. An onsite escort will be required for every trip to and from the work area. The CDM field crew will remain in radio contact with RIAC while onsite. CDM will inform RIAC at least two weeks prior to mobilization to the site so that RIAC has sufficient time to inform the appropriate facilities' officials regarding the length and type of pending field work.

3.2 Disposal of Investigation Derived Waste

The field activities discussed in Section 2 will generate solid and liquid by-products or wastes from such sources as drill cuttings, purged formation water, decontamination, disposable equipment, and protective clothing. Contractors will be required to dispose of wastes generated by their activities, in accordance with RIDEM Division of Site Remediation Policy Memo 95-01, Guidelines for the Management of Investigative Derived Wastes (IDW), included as Appendix B, any other applicable regulations regarding disposal of materials classified as hazardous waste, and the guidelines listed below.

1. All IDW generated during this investigation will be stored in DOT-approved 55-gallon drums. As necessary, drums containing liquid will be overpacked to minimize spillage.

2. Excess drill cuttings generated during sample collection will be drummed. The material will be characterized and transported off-site for disposal at an approved facility. It is estimated that no more than five cubic yards of cuttings will be generated.

3. Liquid wastes generated during sample collection or routine decontamination will be drummed. The contractor will be responsible for characterizing all liquids and submitting all appropriate samples for laboratory analysis. The contractor shall treat or dispose of liquids characterized as hazardous at an appropriate facility. In the case of water containing contaminant concentrations below the respective federal MCLs, the contractor may discharge such waters at an on-site location, after review of analytical data by CDM and concurrence by DEM.

4. Disposable personal protective equipment utilized by field personnel will be collected in polyethylene bags and disposed at a sanitary landfill.

3.3 Contingency Planning and Notification

A health and safety plan (HASP) will be developed for the field program. If hazardous materials or conditions are encountered that require a greater level of PPE, then. Current site data and the work assignment scope of work do not indicate that the proposed field activities will have the potential for imminent and substantial threats to human health. In the event that such conditions do arise, CDM will verbally notify RIAC immediately and the work will be suspended until the conditions can be assessed and the site HASP will be amended to reflect these conditions. The HSP addresses emergency response and notification procedures in detail, in the event of accidents or injuries.

3.4 Wetland Impact Mitigation

No adverse impacts to wetlands are anticipated to occur as a result of this project. The following precautions will be taken to prevent impacts to wetland resource areas:

- Hay bales will be installed before the borings and test pits are initiated on the down gradient side of the borings to prevent migration of sediments into wetland resources.

- A supply of "speedy dry" oil absorbent pads, or an approved equivalent, will be maintained with the drilling and excavation equipment at all times which will be used to contain any accidental release of oil or other petroleum products during field work.

- Boring and test pit locations will be backfilled to existing grades with drill cuttings or excavated soil. CDM representatives will be on site throughout drilling to verify the contractor adheres to these conditions.

Appendix A

CDM Standard Operating Procedures

STANDARD OPERATING PROCEDURES

FIELD PROCEDURES

SOP-FL-001
FIELD LOG BOOK CONTENT

1.0 INTRODUCTION

Information recorded in field log books include observations, data, calculations, time, weather, description of the data collection activity, methods, instruments, and results. Additionally, the log book may contain descriptions of wastes, biota, geologic material, and site features including sketches maps, or drawings as appropriate.

2.0 PREPARATION

In addition to this SOP, site personnel responsible for maintaining log books must be familiar with other pertinent SOPs. These should be consulted as necessary to obtain specific information about equipment and supplies, health and safety, sample collection, packaging, decontamination, and documentation. These procedures should be located at the field office.

Prior to use in the field, each log book should be marked with a specific control number. The field notebook will then be assigned to an individual responsible for its care and maintenance.

Field log books shall be bound with lined, consecutively numbered pages. All pages must be numbered prior to initial use of the log book. The following information shall be recorded inside the front cover of the log book:

- Field log book document number
- Activity (if the log book is to be activity-specific)
- Person and organization to whom the book is assigned, and phone number(s)
- Start date

The first five pages of the log book shall be reserved for a table of contents. Mark the first page with the heading and enter the following:

TABLE OF CONTENTS

Date/Description	Page
(Start Date)/Reserved for TOC	1-5

The remaining pages of the Table of Contents will be designated as such with "TOC" written on the top center of each page.

3.0 OPERATION

The following is a list of requirements that must be followed when using a log book:

- Record work, observations, quantities of materials, calculations, drawings, and related information directly in the log book. If data-collection forms are specified by an activity-specific plan, this information need not be duplicated in the log book. However, any forms used to record site information must be referenced in the log book.

- Do not start a new page until previous one is full or has been marked with a single diagonal line so that additional entries cannot be made. Use both sides of each page.

- Do not erase or blot out any entry at any time. Before an entry has been signed and dated, any changes may be made but care must be taken not to obliterate what was written originally. Indicate any deletion by a single line through the material to be deleted.

- Do not remove any pages from the book.

- Record as much information as possible.

Specific requirements for field log book entries include:

- Initial and date each page.

- Sign and date the final page of entries for each day.

- Initial and date all changes.

- Multiple authors must sign out the log book by inserting the following:

  Above notes authored by:

  - (Sign name)
  - (Print name)
  - (Date)

- A new author must sign and print his/her name before additional entries are made.

- Draw a diagonal line through the remainder of the final page at the end of the day.

- Record the following information on a daily basis:

  - Date and time
  - Name of individual making entry
  - Description of activity being conducted including station (i.e., well, boring, sampling location number) if appropriate
  - Weather conditions (i.e., temperature, cloud cover, precipitation, wind direction, and speed) and other pertinent data
  - Level of personnel protection to be used

Entries into the field log book shall be preceded with the time (written in military units) of the observation. The time should be recorded frequently and at the point of events or measurements that are critical to the activity being logged. All measurements made and samples collected must be recorded unless they are documented by automatic methods (e.g., data logger) or on a separate form required by an operating procedure. In these cases, the log book must reference the automatic data record or form.

At each station where a sample is collected or an observation or measurement made, a detailed description of the location of the station is required. Use a compass (include a reference to magnetic declination corrections), scale, or nearby survey markers, as appropriate. A sketch of station location may be warranted. All maps or sketches made in the log book should have descriptions of the features shown and a direction indicator. It is preferred that maps and sketches be oriented so that north is towards the top of the page.

Other events and observations that should be recorded include:

- Changes in weather that impact field activities.

- Deviations from procedures outlined in any governing documents. Also record the reason for any noted deviation.

- Problems, down-time, or delays.

- Upgrade or downgrade of personnel protection equipment.

4.0 POST-OPERATION

To guard against loss of data due to damage or disappearance of log books, copies of completed pages shall be periodically (weekly, at a minimum) and security stored at the field office. Documents which are separated from the log book shall be copied and submitted regularly and as promptly as possible to the field office. This includes all automatic data recording media (print-outs, logs, disks or tapes) and activity-specific data collection forms required by other SOPs.

At the conclusion of each activity or phase of site work, the individual responsible for the log book will ensure all entries have been appropriately signed and dated, and that corrections were made properly (single lines drawn through incorrect information, then initialed and dated). The completed log book shall be submitted to the field office records file.

SOP-FL-002
SAMPLE DOCUMENTATION AND IDENTIFICATION

1.0 INTRODUCTION

The following procedures describe proper documentation to be included in field notebooks. Documentation includes describing data collection activities, logging sample locations, sample IDs, container labeling and chain-of-custody forms (see SOP-FL-013). Procedures for sample classification to insure proper labeling of samples are also included.

2.0 RESPONSIBILITIES

The field geologist/field inspector is required to oversee drilling of the boreholes, installation of monitoring wells, sample soils and groundwater, fill out field book logs, soil boring logs, monitoring well logs, submit samples for analysis, COC forms and labeling of drums. Also, the field geologist/field inspector is required to adhere to the Site Specific Health & Safety Plan. Drilling inspectors must record Health and Safety monitoring performed during drilling activities. Field book entries should state starting time of monitoring, equipment used and results.

The field geologist/field inspector will be notified by the site manager of the following:

- When and where to implement contingency borings so the extent of subsurface contamination may be better defined.
- When to request accelerated turn around times for laboratory analysis of samples. This may be the result of project schedule, excessive contamination that requires TCLP analysis, or other reasons.
- Which samples to hold for TCLP analysis.
- When to install additional groundwater monitoring wells due to evidence indicating the presence of floating product.
- When to change the sampling strategy because of contamination, borehole depth, or variation in material types.
- In order for the site manager to make the above described decisions, communication between the field team and the site manager must be thoroughly maintained.

2.0 FIELD NOTEBOOKS

Complete and thorough logging of field events is essential to a timely and accurate completion of this project. The field geologist/field inspector is responsible to account for particular actions and times for these actions of the contractor while in the field. Also, sample identification (numbers and descriptions) of field samples, duplicates samples and blank samples should also be accounted in the field book. For a particular workshift, the field book should contain the following:

- Field personnel name, contractors name, number of persons in crew, equipment used, weather, date, time, and location at start of day (boring number).
- Sample identification number, depth, time, blow counts, amount of sample recovery in split-spoon sampler, HNu or OVM reading and burmeister soil descriptions.
- Description of any unusual surface or subsurface soil conditions
- Record of Health and Safety monitoring; time, equipment and results
- Record of site accidents or incidents
- Record of any visitors
- Potential of delays
- Materials (grout, well screen, etc.) and equipment used during borehole/well installation
- Final daily tally of work completed including list of samples obtained
- Completion of daily QA/QC log sheet
- Contractor downtime, decontamination time, equipment breakdowns, movement tracking throughout the day, etc.
- Any other data that may be construed as relevant information at a later date.

The field logs should confirm the contractor's data including billing, boring logs, etc. Field notes should be photocopies weekly and returned to the site area manager by the field supervisor.

In addition, the field personnel are responsible to complete a sample log form for each boring or test pit. This log form is considered a deliverable to the client and must be complete, accurate and organized. These forms should be completed so as not to require future reference into the field books. Note observations on these forms (oil odor, etc.). These forms are to be filled out upon completion of a particular borehole. These logs are simply a sectional view of the borehole generated from the data contained in the field book.

If a borehole is completed as a monitoring well, simply note this on the form, and complete the monitoring well log. Examples of completed boring logs should be reviewed and adequate blank log forms obtained.

Monitoring well logs are required in addition to the boring log form if the borehole is completed as a monitoring well. These are to be completed in the field after a monitoring well is installed. They should include data such as screen length, riser length, materials used, etc. Examples of monitoring well logs should be reviewed and adequate blank log forms obtained.

3.0 DRUM LABELING

Labeling of drums is essential for tracking hazardous materials. Although it is the contractor's responsibility to collect, handle, and store the drums, it is the responsibility of field personnel to label these drums appropriately. There is a significant cost implication if drums are not property labeled. Unknown material must be disposed of as hazardous waste if any hazardous waste is found on-site.

The following drum labeling procedures are to be adhered to:

- Field staff shall adhere packing list envelopes to the side of the drum(s) at the completion of a boring.
- Field staff shall print with an indelible marker on information cards all information pertaining to the contents of the drum(s). If more than one drum is collected from the same borehole, each information card shall be numbered sequentially in parenthesis starting with the number one after the boring number. The information shall include:
  - Program Area
  - Boring No.(s)
  - Date collected
  - Description of contents (i.e., soil cuttings, well water, etc.)
  - Amount of water (specify in inches)
  - Fullness of drum (not including free liquid, specify in fractional form)
- Field staff shall insert information card into packing list envelope. The packing list envelope shall be sealed at this time.
- Field staff shall record in field book all information pertaining to the contents of the drum that was printed on the information card.
- Program manager, upon receipt of the analytical data for the drums, shall prepare a summary table of the analytical results on a weekly basis, and provide the designated coordinator.
- Based on the tabulated information the designated coordinator will determine and prepare the appropriate storage labels required:
  - Hazardous Waste label
  - Non-hazardous label
- The designated coordinator will fill out these labels.
- Field staff shall adhere these labels to the appropriate drums. If the information cards inside the packing list envelopes are found to be damaged they shall also be reprinted at this time.

4.0 SAMPLE IDENTIFICATION

The sample identification process is a logical labeling of the samples collected for analysis. The samples should be labeled according to the example below:

CDM - SB - 035 - 001
CDM - MW - 03 - 001
CDM - SB - 035 - 003

Where:
- CDM = for Camp Dresser & McKee
- SB = Soil Boring
- 035 = Borehole Number
- 001 = Sample Number (This must be identified on the COC)
- MW = Represents groundwater sample from Monitoring Well

SOP-FL-003
SAMPLE PRESERVATION

1.0 INTRODUCTION

Methods of preservation are generally intended to retard biological action, to retard hydrolysis of chemical compounds and complexes, to reduce volatility of constituents, and to reduce absorption effects. Preservation methods include pH control, chemical addition and refrigeration. Analytical methods commonly employed are listed in Table 1.

Sampling and preservation or samples, including required volumes and holding times are presented in Table 2. The required minimum sample volume, sample containers and analytical holding times for each analysis is also presented in Table 2.

(2) Plastic (P) or Glass (G). For metals, polyethylene with a polypropylene cap (no liner) is preferred.

(3) Holding times listed are recommended for properly preserved samples based on currently available data.

SOP-FL-005
CHAIN-OF-CUSTODY PROCEDURES

1.0 INTRODUCTION

This section describes the procedures used to ensure that sample integrity and chain-of-custody are maintained throughout the sampling and analysis program. Chain-of-custody procedures (COC) provide documentation of sample handling from the time of collection until its disposal by a licensed waste hauler. This documentation is essential in assuring that each sample collected is of known and ascertainable quality.

The chain-of-custody begins at the time of sample collection. Sample collection is documented in the field notebooks in accordance with the specified SOP. At the same time, the sampler fills out the label on the sample container with the following information:

- Sample ID code
- Sampler initials
- Date and time of sample collection

A "Chain-of-Custody Record" form is filled out for each sample type at each sampling location. Each time the samples are transferred to another custodian or to the laboratory, the signatures of the people relinquishing the sample and receiving the sample, as well as the time and date, are documented. Labels will be filled out with an indelible, waterproof, marking pen.

A sample Chain-of-Custody Record is shown in Figure 1. The actual chain-of-custody record is a three part form. The original form is retained by the laboratory. The person relinquishing the samples keeps a copy of the form at the time of sample submittal. This form is then returned to the site manager or person in charge of data coordination.

The Chain-of-Custody Record will be placed in a Ziplock bag and placed inside of all shipping and transport containers. All samples will be hand delivered or shipped by Federal Express to the laboratory specified by the Sampling and Analytical Coordinator. Samples should be packed so that no breakage will occur.

FIELD QUALITY CONTROL SAMPLES

1.0 INTRODUCTION

In order to maintain quality assurance and quality control in both the field and the laboratory, additional samples such as trip blanks, duplicates, field blanks, split samples, performance evaluation samples and background samples will be collected. Each type of QA/QC sample is described below.

2.0 QUALITY CONTROL FOR SOIL SAMPLING

Approximately 10 percent of all soil samples analyzed should be QA/QC samples. The exact percentage will be specified in the QAP. These samples act as a verification of appropriate field and laboratory procedures. These samples should be recorded in the field book but should not be identified on the Chain-of-Custody (COC) form other than with an MD (Miscellaneous Discrete). All QA/QC samples should be numbered sequentially with other field samples on the soil log form. The following is a breakdown of types of QA/QC samples that are to be taken:

2.1 Duplicate Samples

Approximately ten percent of all soil samples analyzed should be duplicate samples. The exact percentage will be specified in the QAP. Soil duplicates shall be field-homogenized soils of UD, LD, or MD samples. To ensure laboratory "blind" analyses, duplicate samples will be recorded as MD samples on sample containers and the COC forms. The actual identification of the duplicate samples shall be recorded in the field book. Duplicate samples are collected from the same split spoon sampler, homogenized in the field and analyzed for the same compounds.

Soil Blanks

Approximately two percent of all soil samples analyzed should be soil blanks. The exact percentage will be specified in the QAP. Soil blanks consist of filling VOA jars with sand that has been certified to be free of all volatile organic compounds. Soil blanks are submitted as "blind" samples to the different laboratories for analysis of volatile organic compounds and will be recorded as MD samples on sample containers and the COC forms. The purpose of these samples is to detect additional sources of contamination that might potentially influence contaminant values reported in actual site samples.

2.2 Water

Rinsate Blanks

Approximately two percent of all soil samples analyzed should be rinsate blanks. The exact percentage will be specified in the QAP. Rinsate blanks are collected after a sample is taken and the equipment used (i.e., split spoon sampler) has been decontaminated. Distilled water is then poured over the decontaminated sampling equipment and collected in sample jars for analysis. It should be documented in the field book which soil sample preceded the rinsate blank and which soil sample followed the rinsate blank for the equipment used. To ensure laboratory "blind analyses", rinsate blanks will be recorded as GW (groundwater) samples on sample containers and the COC forms.

QA/QC Log Sheet

At the end of each day a QA/QC sample log sheet should be completed by the field supervisor and forwarded to the site manager. The laboratory does not receive a copy of this QA/QC sheet.

3.0 QUALITY CONTROL FOR GROUNDWATER SAMPLING

Approximately ten percent of all groundwater samples analyzed should be QA/QC samples. The exact percentage will be specified in the QAP. These samples act as a verification of appropriate field and laboratory procedures. These samples should be recorded in the field book but should not be identified on the COC form as a QA/QC sample. All QA/QC samples should be numbered sequentially with other field samples. The following is a breakdown of types of QA/QC samples that are to be taken:

3.1 Duplicate Samples

Approximately ten percent of all groundwater samples analyzed should be duplicate samples. The exact percentage will be specified in the QAP. To ensure laboratory "blind" analysis, duplicate samples will be recorded with the well I.D. number and the next sequential sample number on sample containers and the COC forms. Duplicate samples are collected from the same bailer and analyzed for the same compounds.

3.2 Trip Blanks

Approximately two percent of all groundwater samples analyzed should be trip blanks. The exact percentage will be specified in the QAP. Trip blanks are VOA vials filled with distilled water prior to going out in the field. These prefilled vials are to be carried with the sample bottles and samples and should remain sealed the entire time. It should be documented in the field book which groundwater samples were collected and transported with the trip blank.

3.3 Rinsate Blanks

Approximately two percent of all groundwater samples analyzed should be rinsate blanks. The exact percentage will be specified in the QAP. Rinsate blanks are collected after a sample is taken and the equipment used (i.e., bailer) has been decontaminated. Distilled water is then poured over the decontaminated sampling equipment and collected in sample jars for analysis. It should be documented in the field book which groundwater sample preceded the rinsate blank and which sample followed the rinsate blank for the equipment used.

4.0 CHAIN-OF-CUSTODY FORMS

The Chain-of-Custody (COC) forms are a paper trail system that follows the samples collected and indicates which laboratory analyses are to be performed on which samples. Each sample should be clearly labeled and listed on the COC. The laboratory will only perform analyses on samples indicated with a UD, UC, LD, or MD, all other samples should be indicated with a "HOLD" designation. By labeling a sample "HOLD", the laboratory will store the sample until further instruction is given. Do not check the request for analyses blocks on the COC for samples designated with "HOLD" Status. **Never indicate duplicate or blank samples on a COC.**

It is the responsibility of the field supervisor to coordinate COC forms and supply copies of all COC to the site manager for data management use.

SOP-FL-007
SOIL BORING LOGS

1.0 INTRODUCTION

Geological logging, as previously defined, includes keeping a detailed record of drilling (or excavating) and a geological description of materials on a prepared form. Geological logs are used for all types of drilling and exploratory excavations and include descriptions of both soil and rock. Accurate and consistent descriptions are imperative.

2.0 LOG FORM

When drilling in soils or unconsolidated deposits, the log should be kept on a standard Soil Boring Log Form (see Figure 1). The following basic information should be entered on the heading of each log sheet:

- Project name and number
- Boring or well number
- Location (approximate in relation to an identifiable landmark; will be surveyed)
- Elevation (approximate at the time; will be surveyed)
- Name of drilling contractor
- Drilling method and equipment
- Water level
- Start and finish (time and date)
- Name of logger

The following technical information is recorded on the logs:

- Depth of sample below surface
- Sample interval
- Sample type and number
- Length of sample recovered
- Standard penetration test (ASTM-D1586) results if applicable
- Soil description and classification
- Graphic soil symbols
- HNu/OVA/OVM readings

In addition to the items listed above, all pertinent observations about drilling rate, equipment operation, or unusual conditions should be noted. Such information might include the following:

- Size of casing used and method of installation
- Rig reactions such as chatter, rod drops, and bouncing
- Drilling rate changes
- Depth and percentage of fluid losses
- Changes in fluid color or consistency
- Material changes
- Zones of caving or heaving

3.0 SOIL CLASSIFICATION

Description of soils (well logging) should be done in accordance with the Unified Soil Classification System (USCS) as described in ASTM D2487-69 (1975): Test Method for Classification of Soils for Engineering Purposes. The approach and format should generally conform to ASTM D2488-69 (1975): Recommended Practice of Description of Soils (Visual-Manual Procedure). Alternatively, the Burmeister system of soil description may be used. Because the Burmeister system relies heavily on handling the soil, it should not be used in areas of severe soil contamination.

The soil description should be concise and should stress major constituents and characteristics. Soil descriptions should be given in a consistent order and format. The following order is as given in ASTM D2488:

- Soil name. The basic name of the predominant constituent and a single-word modifier indicating the major subordinate constituent.
- Gradation or plasticity. For granular soil (sands or gravels) that should be described as well-graded, poorly graded, uniform, or gap-graded, depending on the gradation of the minus 3-inch fraction. Cohesive soil (silts or clays) should be described as nonplastic, slightly plastic, moderately plastic, or highly plastic, depending on the results of the manual evaluation for plasticity as described in ASTM D2488.
- Particle size distribution. An estimate of the percentage and grain-size range of each of the soil's subordinate constituents with emphasis on clay-particle constituents. This description may also include a description of angularity. This parameter is critical for assessing hydrogeology of the site and should be carefully and fully documented.
- Color. The color of the soil using Munsell notation.
- Moisture content. The amount of soil moisture, described as dry, moist, or wet.
- Relative density or consistency. An estimate of density of a granular soil or consistency of a cohesive soil, usually based on standard penetration test results (see Table 1).
- Soil texture and structure. Description of particle size distribution, arrangement of particles into aggregates, and their structure. This description includes joints, fissures, slicken-sides, bedding, veins, root holes, debris, organic content, and residual or relic structure, as well as other characteristics that may influence the movement or retention of water or contaminants.
- Relative permeability. An estimate of the permeability based on visual examination of materials (e.g., high permeability for coarse sand and gravel versus low permeability for silty clay). The estimate should address presence and condition of fractures (open, iron-stand, calcite-filled, open but clay-lined, etc.), as well as fracture density and orientation.

TABLE 1

RELATIVE DENSITY OF NONCOHESIVE SOIL

Blows/Ft	Relative Density	Field Test
0-4	Very loose	Easily penetrated with 1/2-inch steel rod pushed by hand
5-10	Loose	Easily penetrated with 1/2-inch steel rod pushed by hand
11-30	Medium	Easily penetrated with 1/2-inch steel rod driven with 5-lb hammer
31-50	Dense	Penetrated a foot with 1/2-inch steel rod driven with 5-lb hammer
>50	Very dense	Penetrated only a few inches with 1/2-inch steel rod driven with 5-lb hammer

CONSISTENCY OF COHESIVE SOIL

Blows/Ft	Consistency	Pocket Penetrometer (TSF)*	Torvane (TSF)	Field Test
<2	Very soft	<0.25	<0.12	Easily penetrated several inches by fist
2-4	soft	0.25-0.8	0.12-0.25	Easily penetrated several inches by thumb
5-8	Firm	0.50-1.0	0.25-0.5	Can be penetrated several inches by thumb with moderate effort
9-15	Stiff	1.0-2.0	0.5-1.0	Readily indented by thumb but penetrated only with great effort
16-30	Very stiff	2.0-4.0	1.0-2.0	Readily indented by thumbnail
>30	Hard	>4.0	>2.0	Indented with difficulty by thumbnail

*TSF -- Tons per square foot.

- Local geologic name. Any specific local name or a generic name (i.e., alluvium, loess). Also use of Unified Soil Classification System of symbols.

The soil logs should also include a complete description of any tests run in the borehole; placement and construction details of piezometers, wells, and other monitoring equipment; abandonment records; geophysical logging techniques used; and notes on readings obtained by air monitoring instruments.

4.0 ROCK CORE LOGGING

The procedure to properly record core logging includes:

- Record the depth of the top and the bottom of the core run.
- Record the core recovery (CR) of each run. The percentage of core recovered is:

$$CR = \frac{\text{Total length of core recovered}}{\text{Total length of core drilled}} \times 100$$

- Designate areas of suspected core loss based on drill behavior and rock quality. Core loss is often indicated by: fragmented core, polishing, circular core ends, rounded edges on core pieces, or immediately beneath hard fragments in soft rock. Routinely placing core loss at the top or bottom of the core run can lead to significant errors during evaluation. Note the reason for core loss, i.e., soft rock - washed away hard rock ground up by drilling, or malfunction of equipment during drilling - mislatch.
- Often a length of core is left at the bottom of the hole and recovered during the next core run. Unless properly handled, this condition may lead to significant errors. The preferred method to correct this situation is to carefully inspect the upper part of the recovered core for marks made by the core catcher or drill bit during the previous run. If they are identified, break the core and insert the run marker at proper location.
- Log the core in as much detail as possible depending upon the local geology and project requirements. The description should include:
  - Rock type
  - Color
  - Grain size
  - Mineralogy
  - Bedding thickness, dip and type (i.e., stylolitic or shale partings)
  - Natural joints and fractures including frequency, dip, second, any coatings or fillings. A graphical representation of these features may also be desirable.

- Additional data in sedimentary rocks includes:
    - Sorting
    - Cementation
    - Density or compaction
    - Rounding

The core should be logged as quickly as possible after removal from the hole. Some materials may degrade rapidly upon exposure, resulting in apparently poor rock, which was not actually present in the subsurface.
Check carefully each core end and try to determine if the fracture is natural or mechanical in origin. Mechanical fractures often can be identified by their orientation, the absence of secondary coatings or filling and slickensides, and its fit with the adjacent core piece. If doubt exists, consider it a natural fracture. If it is determined that the fracture is mechanical, ignore it and consider the two pieces of core as a single piece.

SOP-FL-008
MONITORING WELL INSTALLATION

1.0 INTRODUCTION

This SOP discusses the aspects of installing monitoring wells. It provides the reader with the methodology for siting monitoring well locations for the standard operating procedures (SAP). It provides procedures for well design and well construction to aid in the development of drilling subcontracts. Drilling operation and well development guidelines are presented to aid the reader in the oversight of the installation of monitoring wells. Additionally, slug test procedures have been outlined in SOP-FL-004 to perform insitu permeability tests on a monitoring well.

The principal reason that monitoring wells are constructed is to collect groundwater samples that, upon analysis, can be used to delineate a contaminant plume and track movement of specific chemical or biological constituents. A secondary consideration is the determination of the physical characteristics of the groundwater flow system to establish flow direction, transmissivity, quantity, etc. The spatial and vertical locations of monitoring wells are important. Of equal importance are the design and construction of monitoring wells that will provide easily obtainable samples and yield reliable, defensible, meaningful information. In general, monitoring well design and construction follows production well design and construction techniques. However, emphasis is placed on the effect these practices may have on the chemistry of the water samples being collected rather than on maximizing well efficiency.

From this emphasis, it follows that an understanding of the chemistry of the suspected pollutants and of the geologic setting in which the monitoring wells are constructed plays a major role in determining the drilling technique and materials used.

2.0 WELL SITING

The following procedures should be followed:

- Review and familiarize oneself with pertinent proposal sections and specifications. Review and familiarize oneself with subcontractors contracts. Review and familiarize oneself with any regulations governing how, where or when the well is drilled. Review and familiarize oneself with data (supplied by the Client, or any other data available) used for program planning.

- Identify well site on a topo map or other suitable project base map. Contact landowner at the beginning of well siting. Inquire whether the proposed drill locations will interfere with the landowner's established land use. Unless the property is wholly owned by the client, then the landowner is always contacted before entering the property, even if he is leasing back the property from the client.

- Check route to insure a drill rig can access the proposed well site. Plan routes which require the least disturbance of natural vegetation or natural countryside conditions and which would not require grading or other types of work by i.e., backhoes, etc.

- The well site should be reasonably level and absent of large boulders or other hazardous obstructions.

- Check to insure absence of buried high pressure gas, or oil or water lines. If any lines are present relocate the well site a safe distance away from them. Be sure to check with the driller to insure his agreement.

- Check to insure absence of overhead power transmission lines. If any overhead power lines are present, relocate the well site a safe distance away from them. Be sure to check with the driller to insure his agreement.

- If practical, make arrangements to have any necessary earthen mud pits excavated prior to setting the rig over the well location. This needs some input by the driller and greatly reduces (in some cases) set up and starting time.

- Stake the well location with a 1/4" x 1" lath marked with the well number and, if known, or if necessary, the total depth (T.D.).

- Pre-drilling (on-site) meeting with drilling and logging contractors. Brief the contractors on access routes to well site locations, numbering sequence, any potential access problems and general T.D. estimates. Establish a chain of command and responsibility for personnel involved. Review project objectives and procedures with contractors.

- Consult landowner about water source and access, then notify the driller of these decisions.

- Explain to the driller the need for care and accurate retrieval of drill cuttings and, if necessary, placement and accounting of materials during well completion. Explain to the geophysical truck operator any specific needs you have or results you require from his equipment such as an expanded natural gamma scale or reduced sensitivity on the spontaneous potential (S.P.) log, etc.

3.0 WELL DESIGN

The following procedures should be followed:

- Examine the geophysical log and determine the exact interval(s) and depth(s) of the completion zone(s). Calculate the quantity of slotted casing or screen, blank casing, sealing materials, gravel pack and cement necessary to complete the well.

- Use a cementing company handbook (e.g., Halliburton or Dowell) to calculate the quantities of gravel pack, sealing materials and cement. If one of these is not available then figuring the volume of the bore hole (r_B2 x L) minus the volume of the casing (r_C2 x L) will yield volume per linear foot.

  A cubic foot of silica sand weighs 100 pounds. Frequently silica sand is packaged in 100 pound sacks but should be purchased and delivered in bulk quantities. A five gallon bucket is equal to 0.67 cubic feet. Dividing the determined or calculated volume between the well bore and the outside of the casing(s) into 0.67 cubic feet per bucket will yield approximately the number of feet per bucket of silica sand. Dividing the total interval of the intended gravel pack by the number of feet per bucket of gravel pack will yield approximately how many buckets of gravel will be required. This same method can be used if the silica sand arrives in 1-cubic foot sacks (100 lbs) except the final value is approximately the number of feet per sack of silica sand.

  Cement usually comes in 94 pound sacks and can be mixed in the field to obtain volumes between 0.88 cubic feet per sack to 1.50 cubic foot per sack. See the table on the next page for the most common cement slurry mixtures.

  The calculation to determine the amount of cement needed for seals, caps or plugs is governed by the volume of mixture per sack desired. This volume should be specified either in the project proposal or the drillers' contract.. If there is any doubt, then consult the hydrogeologist in charge. Determine the amount of cement in the same manner as the silica sand calculation for the gravel pack.

  Clay seals are routinely placed in a well completion above the gravel or filter pack and below the cement or grout cap or plug. The clay seals are generally a bentonite clay and before swelling (in the bore hole) has the form of 1/4" to 1/2" tablets. A common type of bentonite tablets are American Colloid Volclay Tablets. The tablets generally come in plastic containers of 20 and 50 pounds but can also arrive in boxes or cloth sacks.

Water-Cement Ratio (gals. water per sack)	Weight per Gallon of Slurry (lbs)	Volume of Mixture per sack (cu. ft.)
7 1/2	14.1	1.50
7	14.4	1.43
6 1/2	14.7	1.35
6	15.0	1.28
5 1/2	15.4	1.21
5	15.8	1.14
4 1/2	16.25	1.08
4	16.50	1.00
3 1/2	17.35	0.95
3	18.1	0.88

The volume of the bentonite tablets needed for a specific seal thickness can is calculated in the same manner as was done for the gravel pack and cement requirements.

These methods of estimating the quantity of materials to be used in any specific well completion are crude at best. There may exist portions of the bore hole that are of a larger diameter, due to erosion during drilling, or sections of a somewhat smaller diameter due to swelling conditions; the estimated quantities seem always to be either too little or too much.

Note: Rig stand-by time, while waiting on supplies, is paid at an hourly rate as is well completion. The more quickly the completion is done the lower the cost per foot for the well.

Measure all materials twice during the well construction. First, when estimating the quantity of supplies needed for the completion, second, during well construction. Keep the first estimate in the daily log book record the actual (second measurement) intervals (tops and bottoms), quantity and type of materials placed in the well recorded on the appropriate forms

4.0 WELL CONSTRUCTION

The following procedures should be followed:

4.1 Final Design of Casing - Screen/Slotted Casing String(s)

If there is any doubt about the final design of the casing string, based on data from the pilot hole or the individual drill holes scheduled for completion, verify the design with the hydrogeologist in charge.

It is the rig hydrogeologist's responsibility to insure adequate supplies are maintained at each well site even though it may be the contractors responsibility for supplying the materials.

4.2 Installing Casing (Slotted/Screen Casing String(s))

1) Plastic or Polyvinylchloride (PVC) Casing -

Join all 10 foot lengths of casing (blank and screen) by flush-joint threading. All pipe is to be cut with a pipe cutting tool which leaves a smooth, square end. Sawing is not permitted.

2) Steel Welded or Standard Threaded - Coupled (STC) Casing -

The steel welded casing-slotted/screen casing string(s) are joined at a smooth, flat joint and welded. Accomplish alignment using both a carpenters level (or other suitable level) and a casing-alignment clamp. If the steel casing is the threaded and coupled-type casing then alignment is insured by not cross-threading the couple and the pipe. Lubricate the joint with a suitable grease and tighten with pipe wrenches, chain tongs or power tongs until the string is screwed together tight enough to prevent unscrewing or shearing out of the threaded joint.

3) A complete casing-slotted/screen casing string tally is kept by both the hydrogeologist and the contractor. Seal the bottom on the casing-slotted/screen casing string with a cap, glued and screwed permanently in place.

4.3 Installing Filter Material (Gravel Pack)

1) Place the filter material downhole using a tremie pipe. The length of pipe should end no more than 20 feet above the bottom of the hole, or the bottom of the interval to receive the filter pack. Gradually lift removing sections of pipe, as the filter material being placed in the hole rises. Check the height of the filter material periodically with the tremie pipe.

2) Mix clean water with the filter material to facilitate its downward movement and to help prevent clogging up the tremie pipe.

3) Place the filter material continuously at a rate which prevents bridging either in the tremie pipe in the bore hole.

4) The filter material shall be installed to levels pre-determined by the hydrogeologist. The exact depth for each well is determined from the final well design. However, generally the top of the filter material will be 5 feet above the top of the highest slotted/screened interval.

5) Following placement of the filter material "sound" or "tag" this depth with the tremie pipe to insure it is at the prescribed level.

4.4 Installing Bentonite Pellet Seals (Blanket)

Following the installation of the filter material place a bentonite pellet blanket seal on top of the filter material to prevent contamination of the filter pack by the grout.

1) The actual amount of the annulus which is filled with bentonite pellets may vary from completion to completion but a minimum of 6 inches of the annulus should be filled with bentonite by gravity feed from the surface. The tremie pipe remains in the bore hold during gravity feed of the bentonite pellets. Calculate the exact volume of pellets needing placement.

2) Following placement of the bentonite pellets the depth is tagged with the tremie pipe to insure they are at the desired level. This is done carefully to prevent plugging of the tremie pipe.

4.5 Grouting

1) Grout the annular space above the bentonite pellets as directed by the hydrogeologist.

2) The grouted volume of annular space will vary from completion to completion, and sometimes within the same completion. Generally, if the annular space exceeds approximately 20 feet then the grouting is done in more than one stage. Take care to insure that the grout does not displace the bentonite seal or exceed (in weight) the collapse strength of the casing.

3) The methods of mixing grout in the field are numerous. The first concern is that the slurry mixture is fluid enough for placement by tremie pipe and heavy enough to give the desired strength and sealing properties required. Reference to the table from Halliburton Cementing Tables, 1979 or some other suitable source for the amount of water per sack, and then measure accurately into a large tub (water trough) or steel pit. Mix the correct number of bags of cement with the water at a rate which prevents, clotting or settling out of dry, unmixed cement. Usually this procedure is accomplished with a portable pump which sucks the water or cement mixture in and then expels it under pressure through a hose which is used in a jetting fashion at the opposite end of the tank, pit or trough.

   Grout also can be mixed using a shovel or hoe. Generally, the grout is placed on the side of the tub, the bag is ruptured, and the cement is slowly added to the water. If the cement has hard spots place on a screen of approximately 1/4" mesh attached to some type of frame which is placed across the mixing tub. The cement is then "filtered" for the larger; hard pieces or blocks.

4) Add, near the end of the mixing stage, approximately 2 to 4 percent calcium chloride. The calcium chloride reduces the curing time for the grout. Less than 2 percent is of little use and in excess of 4 percent will not decrease the curing time beyond an optimum period. However, an excess (greater than 4 percent) will not harm the system either. Sometimes it is also desirable to mix approximately 2 percent Bentonite with the cement. This percentage of bentonite offsets shrinkage in the grout when it hardens.

5) Pumping or Pouring Grout

Place the mixed grout above the bentonite pellets. The time between placement of the bentonite pellets and the grout should not be less than 15 to 20 minutes. This allows the pellets to settle to the top of the gravel pack and to begin to swell, while not allowing the grout to harden.

a) The grout can either be pumped down the tremie pipe by same pump used for jetting or it can be poured by buckets through a funnel into the tremie pipe. Displacement of the bore hole fluid is almost certain because the grout slurry weighs more than the residual borehole fluid (10 or 11 pounds per gallon for the mud versus 14 to 18 pounds per gallon for the grout).

b) Except under rare circumstances, grout is never poured from the surface nor is it ever poured into standing water.

c) Following pumping, or placement, of the grout seal, rinse the pipe with clear water and remove. Rinsing is accomplished by pouring clear water behind the grout prior to pulling the tremie.

d) Grout the remainder of the hole by gravity feed from the surface as directed by the hydrogeologist. The quantity of grout placed from the surface should not exceed the collapse strength of the casing and should not be initiated prior to the curing of the grout seal above the bentonite pellets.

e) The best documentation of well construction is to geophysically log the completed well using Density and Natural Gamma techniques. These curves will allow depth-verification of gravel pack, bentonite and grouted intervals in addition to the actual depth to the protective cap at the bottom of the casing-slotted/screen casing string. This technique is limited to materials other than steel casing strings and to budget constraints.

5.0 DRILLING OPERATIONS

5.1 Drilling

If the drill hole was initially drilled as a pilot hole or core hole then it may need reaming to a larger diameter to facilitate construction as a production/monitoring well. The diameter will depend on several factors and may vary from project to project. The ultimate responsibility for hole diameter is a combination of the needs of the hydrogeologist in charge and rig capabilities.

At the onset of reaming record starting time and date on the well construction form or diagram. Then continue documenting the logging and well completion.

5.2 Documentation

Documentation is imperative when drilling. Drilling data is recorded on the soil boring log form. Daily activities of the drill crew and supervisor are essential for keeping within cost guidelines and to identify potential completion problems. Record daily field activities in the field log book. (Problems encountered while drilling are usually charged at the hourly rig rate so that accurate records are necessary. Drilling is generally paid by the foot. Recording the time of start-up and completion as well as total hole depth is mandatory.)

Record rig activities during the drilling of the well. The following:

1) Start-up and shut-down time for the day and visitors at the site.

2) Problems encountered during the day (e.g. slow drilling, thunder storms, down time due to maintenance, waiting on water, injuries and important conversations, decisions made during the day, or any other item which slows or stops drilling).

3) Penetration rate and problems with swelling clays or caving sand or gravel.

4) Type of bit(s) and materials used (bentonite, foam, etc.) and quantity used during drilling (Identify zones where circulation was lost or where water production is observed (or increases) when drilling with air).

5) Sampling of drill cuttings is often performed by one of the drill crew. Ask the crew to collect cuttings samples approximately every five feet unless otherwise specified. Capture samples utilizing a screen-type strainer placed in the path of the discharging mud as it emanates from the borehole. When drilling with air injection, collect cuttings samples near the run of the deflector shield. (Do not wash samples extruded with air injection). Insure that the samples (when drilling with mud) are carefully washed, using clear water, prior to describing them. After description, label each bag completely and place in sequence (of increasing depth) in cuttings' boxes. Sample bags labels should have following minimum information:

   - The sample interval
   - Well number
   - Project name and number
   - Name of investigator

6) Additional data listed below is included on a separate form or forms, but should always be recorded and filed with the hole's drilling history:

   - Hole size
   - Type of drilling
   - Drilling fluid
   - Penetrating rate
   - Circulation losses or gains
   - Drill behavior
   - Drillers observations
   - Sampling intervals
   - Caving, swelling or squeezing intervals

7) Record lithologic character versus depth data as completely and as accurately as possible as the material changes. These descriptions typically include:

- Rock type
- Color
- Mineralogy, including secondary mineralizations

8) Additional data in sedimentary rocks includes:

- Sorting
- Cementation
- Density or compaction
- Rounding

9) During logging relate materials to geologic origin, if possible, i.e., glacial till, stream terrace, buried channel, Fort Union Formation, etc., including:

- Rock type
- Color
- Grain size
- Mineralogy
- Bedding thickness, dip and type (i.e., stylolitic or shale partings).
- Natural joints and fractures including frequency, dip, second, any coatings or fillings. A graphical representation of these features may also be desirable.

10) Additional notes to be recorded include:

Log the core or cuttings as quickly as possible after removal from the hole. Some materials may degrade rapidly upon exposure, resulting in apparently poor rock, which was not actually present in the subsurface.

Check carefully, if logging core, each core end and try to determine if the fracture is natural or mechanical in origin. Mechanical fractures often can be identified by their orientation, the absence of secondary coatings or filling and slickensides, and its fit with the adjacent core piece. If doubt exists, consider it a natural fracture. If it is determined that the fracture is mechanical, ignore it and consider the two pieces of core as a single piece.

Wet samples are contained in sealable plastic bags. Double bag each sample putting the sample tag between the first and second bag.

11) Description of drill cuttings will contain at least the following parameters:

- Rock type
- Color
- Grain size
- Sorting
- Cementation
- Density or compaction

- Rounding
- Mineralogy
- The Total Depth (TD) of the drill hole should be determined and conveyed to the driller as early as possible - preferably before drilling begins. However, this is not always the case and every effort should be made to determine TD as soon as practicable.

5.2 Cleaning

Circulating to clean the drill hole out prior to removing the drill pipe is imperative. Once TD is determined and the depth is obtained, the driller should pull the drill up a short distance (1/4 - 2 feet) from the TD and continue to circulate with whatever fluid the hole was drilled with for a reasonable length of time. This action is to remove any drill cuttings which may have remained in suspension, or were in trans, at the time TD was obtained. Significant accumulation of drill cuttings may occur on the bottom of the drill hole if circulation is not accomplished. This can prevent logging the lower portion of a zone, which could be an important part of the well construction, or may be important for correlation purposes.

Use the sample screen to quickly check the amount of drill cuttings which are being removed during the circulation period. A small amount of cuttings are acceptable. Usually for shallow holes, 150-250 feet in depth, a circulation period of 10 to 15 minutes is adequate. This brief period of circulation insures that both the geophysical logging and completion of the hole as a production or monitoring well is consummated without delay. Circulation precludes delays caused by running the drill pipe back into the drill hole to remove sloughing or other fill at the bottom of the hole. Other problems may also occur, such as hanging the geophysical tool up or wedging in several hundred feet of well casing which can prove to be very costly in either retrieval attempts or redrilling of the hole.

SOP-FL-009
MONITORING WELL DEVELOPMENT

1.0 INTRODUCTION

All completed wells, whether the production or monitoring type, must be developed in order to facilitate unobstructed and continuous groundwater flow into the well. Well development is the process of cleaning the fines from the face of the borehole and the formation near the well screen. During any drilling process the side of the borehole becomes smeared with drilling mud, clays or other fines. This plugging action substantially reduces the permeability and retards the movement of water into the well screen. If these fines are not removed, especially in formations having low permeability, it then becomes difficult and time consuming to remove sufficient water from the well before obtaining a fresh groundwater sample because the water cannot flow easily into the well.

In the construction of high-capacity production type water wells, the development process is an important step to assure maximum hydraulic efficiency. Even though hydraulic efficiency is not a prime consideration in the construction of monitoring wells, nevertheless, development should be performed.

Development is required for the following reasons:

- To restore the natural permeability of the formation adjacent to the borehole to permit the water to flow easily into the screened zone
- To remove the clay, silt and other fines from the formation so that during subsequent sampling the water will not be turbid or contain suspended matter which can easily interfere with chemical analysis

The development process is best accomplished for monitoring wells by causing the natural formation water inside the well screen to move vigorously in and out through the screen in order to agitate the clay and silt, and move these fines into the screen. The use of water other than the natural formation water is not recommended.

2.0 PROCEDURES

1) Compressed air pumped down a pipe inside the well casing can be used to blow water out of the monitoring well. If air is applied to the well intermittently and for short periods then the water is only raised inside the casing rather than blown out and will fall back down the casing causing the desired back washing action. Also, blowing the water out will remove the fines brought into the screen by the agitating action.

2) Considerable care must be exercised to avoid injecting air into the well screen. Such air can become trapped in the formation outside the well screen and alter subsequent chemical analyses of water samples. For this reason, the bottom of the air pipe should never intercept the screen.

3) Another restriction on the use of air is the submergence factor. Submergence is the feet of water above the bottom of the air pipe while pumping (blowing water out) divided by the total length of the air pipe. Submergence should be on the order of at least 70 percent, which may be difficult to achieve with many shallow monitoring wells.

3.0 ALTERNATIVE METHODS

Alternative well development methods may be used including:

- Surge Block - A surge block is a round plunger with pliable edges such as belting that will not catch on the well screen. Moving the surge block forcefully up and down inside the well screen causes the water to surge in and out through the screen accomplishing the desired cleaning action. Surge blocks are commonly used with cable-tool drilling rigs, but are not easily used by other types of drilling rigs.

- Bailer - A bailer sufficiently heavy that it will sink rapidly through the water can be raised and lowered through the well screen. The resulting agitating action of the water is similar to that caused by a surge block. The bailer, however, has the added advantage of removing the fines each time it is brought to the surface and dumped. Bailers can be custom-made for small diameter wells, and can be hand-operated in shallow wells.

- Surging and Pumping - Starting and stopping a pump so that the water is alternately pulled into the well through the screen and backflushed through the screen is an effective development method. Periodically pumping to the surface will remove the fines from the well and permit checking the progress to assure that development is complete.

Well development should continue until the water becomes free of sediment or contains sediment in a lesser amount than was initially present. Conductivity, pH, temperature and turbidity (as measured by a turbidity meter) of the development water must all have stabilized prior to ceasing development. Disposal of development water is site specific and should be discussed in the Sampling and Analysis Plan or Work Plan.

SOP-FL-011
MONITORING WELL WATER LEVEL MEASUREMENT/EXTRACTION

1.0 INTRODUCTION

Water levels are measured for several key reasons. The most common is to provide the basis of understanding groundwater flow pathways, in terms of both horizontal and vertical gradients. Following level measurements, sampling proceeds in a specific order of activity.

2.0 EQUIPMENT

All equipment should be assembled, calibrated, and tested before arriving at the site. All items which potentially come in contact with the ground water samples should be pre-cleaned. Between sampling locations, all items which come in contact with sample water should be either disposed of or thoroughly cleaned. All apparatus, buffers, and samples should be kept out of direct sunlight to avoid temperature fluctuations, particularly pit buffers.

Lay out all equipment on the plastic drop cloth adjacent to the sampling location, to prevent contamination of or from the outside environment. A truck tailgate provides an excellent equipment bench, if the site is accessible to vehicles.

A list of equipment necessary for sampling of monitoring wells at hazardous waste sites is given below.

2.1 Well Evacuation and Sample Withdrawal

- Disposable chemically inert gloves (separate pair for each sampling location).
- A sampler apparatus (e.g., Kemmerer, Bailer) with a capacity to collect 750 to 1000 ml of sample per trip, including sample transfer tubing.
- A 500 foot or more length of steel cable marked in 5, 25, and 100 foot increments on a retrieval system for use with the Kemmerer or Bailer. (Nylon line can be used only if it is not used between wells and only if it can be shown the line will not cause sample contamination.)
- Pump and Power supply (if needed).

2.2 Field Measurements

- Tape measure marked in tenths and hundredths of feet.
- Calibrated M-scope or similar water level recording device.
- Dissolved oxygen meter with an accuracy of ± 0.1 mg/l, if needed.

- Thermometer or temperature measuring device calibrated in °C (degrees centigrade) with an accuracy of $\pm$1°C.
- pH meter with an accuracy of $\pm$0.1 pH units.
- At least two pH buffer standards with pH value below and pH value above the limits anticipated for the samples.
- Conductivity (specific conductance) meter preferably with the capacity to report conductivity (micromhos/cm) corrected to 25°C. Functional range of 0 to 50,000 umhos/cm.
- Beaker for field measurement of pH, conductivity, etc.
- Any additional project-specific sampling equipment as required.

2.3 Sample Preparation

- Field filter apparatus 0.45 micron membrane filters are used only for samples collected for dissolved inorganic analyses.
- A pressure-suction filtration apparatus capable of at least 250 ml volume filtration at any one time.
- Precleaned, capped sample containers containing the appropriate sample preservations, if necessary.
- Tightly capped, securely stored containers holding appropriate preservatives, if necessary.
- Pipet or "squeeze" bottle for preservative additions if such additions are needed.

2.4 Sample Containers

- Precleaned, capped sample containers.
- Ice chest(s) with lock-proof liner to hold collected water samples, and ice or "blue ice".
- Vermiclite.
- Leak-proof liners for ice-chest(s).
- Labeling and Shipping:
- Water resistance sample bottle labeling materials.
- Laboratory instructions.

- Shipping labels, including DOT labels, waste identification, and "This end up" labels, as appropriate.
- Shipping papers, as provided by carrier or regulatory agency.
- Packing tape.

2.5 Cleaning between Sampling Locations

- Laboratory (phosphate-free) detergent.
- Reagent-grade methanol (one to several gallons, depending on amount of equipment to be cleaned, number of sampling locations, and levels of contamination).
- Distilled water, generally about 2 gallons per sampling location.
- Buckets (sufficient for each cleaning liquid and for size of equipment to cleaned).
- Brushes for cleaning inside of bailer, beakers, etc.
- Handiwipes, disposable after each use.
- Plastic sheeting at least one large sheet for each sampling location, for clean layout of equipment.

2.6 Record-keeping

- Prepared field record-sheets for entering data collected in the field.
- Photographic record, if appropriate.
- Chain-of-custody.

3.0 EQUIPMENT CLEANING

All items which potentially come in contact with ground water at the sampling location should be pre-cleaned.

Between sites, sampler cleaning is to be performed immediately prior to sampling from any well. Any portion of the sampling device which contacts contaminated water shall be cleaned or disposed of between wells. Where pumps are used, short sections of sample tubing may be disposed of rather than cleaning. The other items which must be cleaned or disposed of between sampling locations include bailers, pumps, probes, beakers and gloves. Equipment must be cleaned following procedures specified in the Sampling and Analysis Plan. Considerations should be given to the following:

4.0 PROCEDURES

1) Prepare field record sheet and record all relevant data.

2) Check the well for above ground damage.

3) Remove the well cap (a wrench may be needed).

4) Lay out equipment on the plastic drop-cloth adjacent to the sampling location, to prevent contamination of or from the outside environment.

5) Measure and record the depth to water and the time of measurement.

6) Measure the total depth of the well.

7) Remeasure and record the depth of water after a lapse of 4 to 8 minutes following initial measurement and record the depth to water and time of measurement.

8) If successive measurements show essentially no difference, continue the sampling procedure. Where the level change is greater than 1/100th ft, delay the remaining procedures until the change observed and recorded is less than that figure.

9) Determine the volume of water in the well (depth of water x cross sectional area).

10) Purge the well. Evacuate water from the well until measurements of temperature and conductivity remain stable, or until 3-10 casing volumes of water are removed.

11) If soundings show sufficient level of recovery, prepare sampling system. If insufficient recovery is noted, allow additional time to collect samples on a periodic schedule which will allow recovery between samplings.

12) Perform any appropriate field testing of groundwater parameters.

13) Withdraw sample(s) according to the procedures for the sampling equipment used.

14) Collect volatile organic analysis samples first, if required.

15) Fill necessary sample bottles completely by allowing sampler discharge to flow gently down the side of bottle with minimal entry turbulence. Cap each bottle as filled.

16) Preserve and/or filter the sample if necessary as stated in the Sampling and Analysis Plan.

17) Check that a Teflon-liner is present in cap if required. Secure the cap tightly.

18) Label the sample bottle with an appropriate tag. Be sure to complete the the tag with all necessary information. Complete chain-of-custody documents and field log book.

19) Place the properly labeled sample bottle in an appropriate carrying container maintained at 4°C throughout the sampling and transportation period.

20) Between sampling locations, all items which come in contact with ground water such as bailers, pumps, cables, tubing, probes, gloves, and beakers must be either disposed of or thoroughly cleaned.

SOP-FL-012
GROUNDWATER SAMPLING

1.0 INTRODUCTION

Low-flow purge and sampling is appropriate at locations where disturbance of the media around the well screen needs to be minimized. A common concern is turbidity in the monitoring wells and the consequent undesirable effects on metals sampling results.

2.0 LOW-FLOW PURGE AND SAMPLING

The low-flow purge and sample method creates less disturbance and agitation in the well, and therefore excess turbidity is not generated during the purging and sampling process. The result is a more rapid stabilization of turbidity and other parameters (pH, temperature, specific conductivity, dissolved oxygen, Eh), and a sample more representative of conditions in the formation is collected.

The low flow purge and sample method consists of using a submersible pump to purge the well at a very low flow rate (0.5 to 1.5 liter/minute). The pump intake is set approximately in the middle of the well screen, with a stagnant water column over the top of the pump. The well is purged at the low rate until the field parameters (temperature, pH, specific conductivity, turbidity, dissolved oxygen, Eh) have stabilized. The sample is then collected directly from the pump discharge at a low flow rate (see Section 2.2).

2.1 Equipment

The following equipment is required:

- Adjustable rate submersible pump (e.g., Grundfos Redi-Flo$_2$ with converter)
- Generator
- Teflon-lined polyethylene tubing
- Filtration apparatus with 0.45 um filter
- Polyethylene sheeting
- Monitoring instrument for measuring pH, turbidity, dissolved oxygen, conductivity, temperature (Horiba U-10 or equivalent)
- Eh (oxidation potential) meter (Orion or equivalent)
- Large, wide-mouth breakers for measuring field parameters
- Photoionization detector or equivalent (PID)
- Electronic water level indicator or equivalent (marked in 0.01 foot increments)

- Nylon stay-ties
- Logbook(s)
- Decontamination supplies specified in Section 2.3 of this SOP:
  - steam cleaner
  - three foot length, 3-4" diameter PVC pipe with end cap
  - (alternative) eight - 5 gallon buckets
  - (alternative) potable water supply
  - (alternative) alconox
  - (alternative) methanol
  - (alternative) de-ionized water
- Sample bottles and preservatives specified in the Quality Assurance Project Plan (QAP)
- Labels and shipping products specified in the QAP
- Personal protective equipment specified in Site Health and Safety Plan

2.2 Procedure

The following describes the sampling procedures for the low-flow sampling method. Equipment calibration, logbook documentation, sample bottle filling and preservation, and shipping will all be conducted in accordance with the procedures specified in the QAP. Personal protective equipment will be donned in accordance with the requirements of the Site Health and Safety Plan (HSP). Wells shall be sampled in the order of least contaminated to most contaminated.

1) Check and record the condition of the well for any damage or evidence of tampering.

2) Remove the well cap.

3) Measure well headspace with a PID and record the reading in the field logbook. For wells installed on a landfill, also measure the headspace with a combustible gas indicator.

4) Measure and record the depth to water with an electronic water level device and record the measurement in the field logbook. Do not measure he depth to the bottom of the well at this time (to avoid disturbing any sediment that may have accumulated). Obtain depth to bottom information from installation information in the field logbook or drilling logs. Calculate volume of the water column as: depth of water column x cross-sectional area of the well.

5) Lay out the polyethylene sheeting and place the monitoring, purging and sampling equipment on the sheeting. To avoid cross-contamination, do not let any downhole equipment touch the ground.

6) Re-check and record the depth to water after approximately 5 minutes. If the measurement has changed more than 1/100th of a foot, check and record the measurement again, then begin well purging.

7) Attach and secure the teflon-lined polyethylene tubing to the low-flow submersible pump. As the pump is lowered into the well, secure the safety drop cable, tubing, and electrical lines to each other using nylon stay-ties placed approximately 5 feet apart.

8) The pump should be set at approximately the middle of the screen. Be careful not to place intake less than 2 feet above the bottom of the well as this may cause mobilization of any sediment present in the bottom of the well. Start pumping the well at 0.5 to 1.5 liters per minute.

9) The water level in the well should be monitored during pumping, and ideally the pump rate should equal the well recharge rate with little or no water level drawdown in the well (the water level should stabilize for the pumping rate). There should be at lest 1 foot of water over the pump intake so there is no risk of the pump suction being broken, or entrainment of air in the sample. Record the pumping rate adjustments and depth(s) to water in the logbook. If the recharge rate of the well is slow and the well is purged dry, then wait until the well has recharged to a sufficient level and collect the appropriate volume of sample with the submersible pump.

10) The well should be purged at a low-flow rate (from 0.5 to 1.5 liters per minute). During purging, monitor the field parameters (temperature, pH, turbidity, specific conductance, dissolved oxygen and Eh) approximately every 3 to 5 minutes until the parameters have stabilized to within 10 percent (plus or minus 5 percent) over a minimum of three readings. Turbidity and dissolved oxygen are typically the last parameters to stabilize. Note: once turbidity readings get below 10 NTUs, then the stabilization range can be amended to 20 percent (plus or minus 10 percent) over a minimum of three readings.

    Readings should be taken in a clean container (preferably a less beaker) and the monitoring instrument allowed to stabilize before collection of the next sample. The Horiba instrument takes the readings consecutively and therefore the process to record all the measurements may take longer than five minutes. If so, measurements should be taken as often as practicable.

11) Once the field parameters have stabilized, collect the samples directly from the end of the tubing. Volatiles and analytes that degrade by aeration must be collected first. The bottles should be preserved and filled according to the procedures specified in the QAP. All sample bottles should be filled by allowing the pump discharge to flow gently down the inside of the bottle with minimal turbulence. Cap each bottle as it is filled.

12) The ratio of "filtered" to "unfiltered" metals will be decided upon based on site conditions and specified in the QAP. The filtered metals samples will be collected into an unpreserved bottle and then filtered with a 0.45 um filter and pumped into a pre-preserved bottle. Document all field procedures used and any pertinent field observations.

13) Samples shall be preserved, labelled, and placed immediately into a cooler and maintained at 4°C throughout the sampling and transportation period. Samples should be labeled, recorded on the chain-of-custody, and shipped according to the procedures specified in the QAP.

14) The pump assembly should be carefully removed from the well. The teflon-lined polyethylene tubing will be dedicated to each well. The tubing should be placed in a large plastic garbage bag, sealed, and labeled with the appropriate well identification number. The tubing will be stored on-site until the next round of sampling.

15) After sampling is complete, measure the total depth of the well.

16) Close and lock the well.

2.3 Decontamination

The pump (including support cable and electrical wires which are in contact with the sample) will be decontaminated by the following procedure:

1) Steam clean the outside of the submersible pump.

2) Pump alconox solution through the inside of the pump. Note: if gross VOC contamination is encountered in the well (e.g., LNAPLs or DNAPLs), then this procedure shall be amended to pumping either methanol, hexane or isopropyl alcohol through the inside of the pump.

3) Pump hot water from a steam cleaner through the inside of the pump. This can be accomplished by placing the pump inside 3 or 4 inch diameter PVC pipe with an end cap. Hot water form the steam cleaner jet will be directed inside the PVC pipe and the pump exterior will be cleaned. The hot water from the steam cleaner will then be pumped from the PVC pipe through the pump and collected into another container. Note: in order to utilize a steam cleaner jet, it must be certified that no additives or solutions have been added to the steam cleaner jet to prevent corrosion.

4) Pump distilled water through the inside of the pump.

All other equipment that comes in contact with contaminated groundwater, and the pump -- as an alternate method, can be decontaminated using the six-step procedure described below:

1) Flush the equipment/pump well with potable water
2) Flush with alconox solution
3) Flush equipment/pump again with potable water
4) Flush with methanol
5) Flush equipment/pump with de-ionized water
6) Allow equipment/pump to air dry.

If this procedure is used to decontaminate the pump, the duration of flushing with de-ionized water shall be sufficiently long to ensure that all methanol has been rinsed out.

Equipment blanks shall be collected at intervals to monitor the decontamination procedures. The specific percentage or number of blanks shall be defined in the QAP.

3.0 RESTRICTIONS/LIMITATIONS

Careful sampling for compound(s) that may be degraded by aeration is necessary to minimize sample disturbance and, hence, analyte loss. The representativeness of this sample, however, is difficult to determine because the collected sample represents a single point, is not homogenized and has been disturbed.

SOP-FL-013
FIELD SAMPLING EQUIPMENT DECONTAMINATION

1.0 GENERAL

In order to generate analytical data of known and defensible quality, adherence to established quality assurance protocol is necessary. This will ensure that samples obtained in the field are representative of the particular environment from which they have been collected and are of satisfactory quality and quantity to meet the project objectives. To achieve this goal, CDM has established the following protocols to maintain consistency in sample collection and handling during hazardous waste site investigations.

The importance of the environmental sample collection process and associated analytical data is demonstrated through integration of this information into the decision-making process. All phases of site remediation rely on the provision of accurate analytical data. These phases include an initial site evaluation, remedial investigation and design phases, human and environmental risk assessments, determination of treatment effectiveness, remedial alternative selection and cost/benefit analysis, and finally, monitoring the results of the remedial action selected.

The following quality assurance/quality control requirements have been established to maintain sample integrity to as great an extent as possible and are applicable for most hazardous site investigations. Their prime objective is maintaining the physical form and chemical composition of the sample and preventing contamination from other sources or changes in contaminant concentration. To meet this objective there must be a measure of control over all sample handling procedures beginning with sampling equipment decontamination procedures and ending with laboratory analysis. This section focuses on the first half of the control process; the procedures leading up to and ending with sample packaging and transport to the laboratory.

2.0 DECONTAMINATION PROCEDURES

In order to reduce risk of transfer of contaminants between sampling locations or to off-site areas, decontamination of personnel and equipment is required. The decontamination procedures shall be established for each site based on the degree of hazard associated with the site and the amount of possible contact with hazardous materials resulting from site work. Final decontamination procedures and layout for field personnel shall be reviewed and approved by the Site Safety and Health Officer.

2.1 Sampling Equipment

Decontamination of the downhole drilling equipment or excavation equipment, including split spoon samplers, augers, rods, backhoe brackets, and portable decontamination equipment (buckets, brushes, etc.) between boreholes shall be performed by steam cleaning equipment, on a decontamination pad, by the drilling or test pit contractor.

During drilling procedures, decontamination of the split-spoon sampler, and other equipment requiring decontamination, is the responsibility of the drilling or test pit contractor. The following is an outline of the procedure in which this is to be performed:

- Scrub all surface of "dirty" equipment with a brush that is consistently submerged in a bucket containing Alconox mixed with tap water. The equipment should be held directly over the bucket during decontamination so it captures all contamination that is adhered to the piece of equipment.
- Rinse the equipment with tap water contained in an adjacent bucket.
- Rinse the equipment with methanol.
- Rinse the equipment with distilled water.

Spoils and decontamination water collected shall be drummed by the drilling or test pit contractor and handled appropriately. Bailers used in groundwater sampling should be cleaned in a similar fashion as split-spoon samplers.

2.2 Equipment and Solutions

Decontamination equipment, materials and supplies are generally selected based on availability, ease of decontamination and disposability. Recommended decontamination equipment is listed in Table 1. Most equipment and supplies can be easily procured. For example, soft-bristle scrub brushes or long-handle brushes are used to remove contaminants. Water in buckets or garden sprayers are used for rinsing. Large galvanized wash tubs, stock tanks, or wading pools can hold wash and rinse solutions. Large plastic garbage cans or other similar containers lined with plastic bags can store contaminated clothing and equipment. Contaminated liquids can be stored temporarily in metal or plastic cans or drums. Other gear includes paper or cloth towels for drying protective clothing and equipment.

Personnel protective equipment, sampling tools, and other equipment are usually decontaminated by scrubbing with detergent-water such as Alconox using a soft-bristle brush followed by rinsing with copious amounts of water. Solvents are usually used with sampling gear, not protective gear. The appropriate decontamination solution must be selected in consultation with an experienced chemist. Clothing which is heavily contaminated or cannot be decontaminated should be properly disposed of.

Insofar as possible, measures should be taken to prevent contamination of monitoring equipment. Monitoring instruments, unless they are splashed, usually do not become contaminated. Once contaminated, instruments are difficult to clean without damaging them. Any delicate instrument which cannot be decontaminated easily should be protected while it is being used.

TABLE 1

RECOMMENDED DECONTAMINATION EQUIPMENT

Some Recommended Equipment for Decontamination Equipment

- Drop cloths of plastic or other suitable materials on which heavily contaminated equipment may be deposited.
- Collection containers, such as polyethylene lined drums for equipment that must be discarded.
- Lined box with absorbents for wiping or rinsing off gross contaminants and liquid contaminants.
- Large galvanized tubs, stock tanks, 5-gallon buckets, or children's wading pools to hold wash and rinse solutions.
- Wash solutions selected to remove contaminants and contaminated wash solutions.
- Rinse solutions selected to remove contaminants and contaminated wash solutions.
- Long-handled, soft-bristled brushes to help wash and rinse off contaminants.
- Paper or cloth towels for drying protective clothing and equipment.
- Metal or plastic cans or drums for contaminated wash and rinse solutions.
- Plastic sheeting, sealed pads with drains, or other appropriate methods for containing and collecting contaminated wash and rinse solutions spilled during decontamination.

Some Recommended Equipment for Heavy Equipment and Vehicle Decontamination

- Storage tanks of appropriate treat- systems for temporary storage and/ or treatment of contaminated wash wash and rinse solutions.
- Drains or pumps for collection of contaminated wash and rinse solutions.
- Long-handled brushes for general exterior cleaning.
- Wash solutions selected to remove and reduce the hazards associated with the contamination.
- Rinse solutions selected to remove contaminants and contaminated wash solutions.
- Pressurized sprayers for washing and rinsing, particularly hard-to-reach areas.
- Curtains, enclosures, or spray booth to contain splashes from pressurized sprays.
- Long-handled brushes, rods and shovels for dislodging contaminants and contaminated soil caught in tires tires and the undersides of vehicles and equipment.
- Containers to hold contaminants and contaminated soil removed from tires and the undersides of vehicles and equipment.
- Wash and rinse buckets for use in the decontamination of operator areas inside vehicles and equipment.

TABLE 1

RECOMMENDED DECONTAMINATION EQUIPMENT (Continued)

Some Recommended Equipment for Decontamination Equipment	Some Recommended Equipment for Heavy Equipment and Vehicle Decontamination
	• Containers for storage and disposal of contaminated wash and rinse solutions, damaged or heavily contaminated parts, and equipment to be discarded.

2.3 Disposal of Derived Waste

All contaminated equipment must be disposed of properly. Clothing, tools, buckets, brushes, and all other equipment that is contaminated must be secured in drums or other containers, labeled, and properly disposed of. Clothing and other equipment not completely decontaminated on-site should be secured in plastic bags before being removed from the site.

STANDARD OPERATING PROCEDURES

INSTRUMENTATION PROCEDURES

SOP-IN-001
PHOTOIONIZATION DETECTOR

1.0 INTRODUCTION

This Standard Operating Procedure (SOP) is specific to the HNu PI 101 and the Thermal Environmental Organic Vapor Monitor Photoionization Detectors (PID). These portable instruments are designed to measure the concentration of trace gases in ambient atmospheres at industrial and hazardous waste sites and are intrinsically safe. The analyzers employ photoionization detectors.

The PID sensor consist of a sealed ultraviolet light source that emits photons which are energetic enough to ionize many trace species (particularly organics) but do not ionize the major compounds of air such as O_2, N_2, CO, CO_2, or H_2O. An ionization chamber adjacent to the ultraviolet lamp source contains a pair of electrodes. When a positive potential is applied to one electrode, the field created drives any ions, formed by absorption of UV light, to the collector electrode where the currents (proportional to concentration) are measured. One major difference between a flame ionization detector (FID) and a PID is that the latter responds to inorganic compounds as well as non methane type organic compounds.

To assess whether the instrument will respond to a particular species, the ionization potential (IP) should be checked. If the IP is less than the lamp energy, or, in some cases, up to 0.2-0.3 electron volts (ev) higher than the lamp energy, instrument response should occur. For example, hydrogen sulfide (IP = 10.5 ev) may be detected with a 10.2 ev lamp, but butane (IP 10.6 ev) will not be detected.

2.0 CALIBRATION

Calibration of all CDM field equipment is performed by qualified personnel trained in calibration techniques for all field items. When a field instrument which requires calibration is obtained from the equipment room, the unit will display a calibration tag denoting the date when the instrument was last calibrated and/or maintained. All field instruments are calibrated each time they leave the equipment facility for a site. A maintenance file is kept for each calibrated field item.

PID and FID detector type instruments come with field calibration kits. A field calibration kit would be used if the instrument is to be kept out at the site for extended periods of time, or if the instrument endures prolonged environmental extremes. In either case, a calibration check standard could be introduced in the instrument to verify it's accuracy. If an instrument will not calibrate or shows improper field operation, it should be sent back to the office, and another instrument reissued. Field personnel should not try to maintain the instruments in the field. If long sampling program is required, be prepared to take more equipment for backup in case of instrument failure. Records and procedures of all calibration techniques are on file at the CDM equipment management facility in Ten Cambridge Center, Cambridge, Massachusetts.

With the instrument fully calibrated, it is now ready for use. Any results obtained should be reported as parts per millions (ppm) as isobutylene. If you need to convert these numbers based on a benzene standard, HNu offers a conversion table which is available from CDM. Important instrument specifications for each PID detector are listed as follows.

HNu PI 101 Performance	OVM Model 580A
range - 0.1 to 2000	0 - 2000
detection limit 0.1 ppm	0.1 ppm

HNu PI 101 Power Requirements	OVM Model 580A
- continuous use, battery >10 hours	8 hours
- recharge time, max >14 hours, 3 hours +	8 hours
- NiCd Battery	Gel Cell Battery

- Unit can be operated on battery charger.
- Both units provide protection circuitry for the battery. This prevents deep discharging of the battery and considerably extends the battery life.

3.0 HNU PI 101

3.1 Procedure

1) Before attaching the probe, check the function switch on the control panel to make sure it is in the off position. The 12 pin interface connector for the probe is located just below the span adjustment on the face of the instrument. Carefully match the slotted groove on the probe to the raise slot on the 12 pin connector on the control panel. Once in line, twist the outer ring on the 12 pin connector until it locks into position (a distinct snap noise will be felt when in place).

2) Turn the function switch to the battery check position. The needle on the meter should read within or above the green battery arc on the scaleplate. The battery, if needle falls below the green arc, should be recharged before any measurements are taken. If the read LED on the instrument panel should come on, the battery needs charging and the unit cannot be operated without a charger.

3) If the battery is functioning properly, turn the function switch to the STANDBY position. If the needle on the instrument does not read 0, then turn the knob on the instrument panel until the needle deflects to the zero point on the meter.

4) Once the zero is confirmed, turn the function switch to the 0-20 position. At this point, the needle will read approximately 0.5-ppm. This reading is normal background for ambient air. For CDM health and safety reasons, the HNU PI 101 should be operated on this range to insure maximum

sensitivity in the work area. The unit, however, has 2 other ranges (0-200), (0-2000) should monitoring be required for other purposes such as headspace analysis etc. where readings could exceed the 0-20 ppm range.

3.2 Limitations

1) AC power lines (high tension lines), or power transformers can interfere with the instruments performance. This situation can be confirmed by noting a deflection of the meter while in the STANDBY position.

2) Environmental factors such as humidity, rain and extreme cold can limit the instruments performance. To verify the "water sensitivity" condition, gently blow in the hole at the end of the probe. If the needle deflects positively (on the 0-20 position) by 2 ppm or more, a water sensitivity problem exists and the unit should be brought into the warehouse for service. HNU PI 101 should be kept out of the rain as much as possible or covered. This will insure longer operating times with less false positive readings.

3) Quenching the detector can limit the instruments performance. This occurs when a compound such as methane at a very high concentration is introduced to the detector. The concentration is so high that the unit does not respond at all or gives a negative reading.

4.0 **OVM 580A**

4.1 Procedures

1) With the unit being fully calibrated before receiving it, you are ready for operation. Located on the right hand side of the unit is a panel. Slide this panel off of the unit. Inside there is a switch which supplies power to the LCD portion of the instrument. Turn this switch on and replace the panel. On the top of the OVM, there is an instrument panel. Locate the on/off switch and turn the unit on. This switch activates the lamp as well as the pump. Turn this switch off when the instrument is not in use, but leave the internal switch on.

2) The unit is now in the operation mode with all readings shown on the LCD display. Options for the OVM 580A include automatic recording and alarm settings. Should any options be required, they can be set up before the instrument leaves the CDM equipment warehouse.

Warning signals associated with the OVM include a Low Battery signal. A flashing B will appear in the left hand corner of the bottom line of the display when the 580A is in the RUN mode. If a gas concentration >2000ppm is detected by the OVM, the top line of the display will show OVERRANGE. Once this occurs, the instrument will "lock out" until the unit is brought to a clean area. A clean area is described as an area where the concentration of organic vapors is below 20 ppm.

SOP-IN-002
FLAME IONIZATION DETECTOR

1.0 INTRODUCTION

The organic vapor analyzer (Foxboro Organic Vapor Analyzer 128) is a portable flame ionization detector package designed to monitor organic gases and vapors in the ambient air.

The instrument measures organic vapor concentration by producing a response to an unknown sample, which can be related to a gas standard used to calibrate the instrument. During instrument operation, a continuous sample is drawn into the probe and transmitted to the detector chamber by an internal pumping system. Inside the detector chamber, the sample is exposed to a hydrogen flame which ionizes the organic vapors. This burning of vapors leaves positively charged carbon-containing ions which are driven to a collecting electrode. A current is generated by this process and measured on an amplifier.

FID's are more sensitive for hydrocarbons than any other class of organic compounds. Compounds containing oxygen such as alcohols, esters, ethers, and aldehydes give lower responses. In general, the higher the proportion of carbon to oxygen the lower the effect of oxygen in lowering instrument response. This same rule applies to nitrogen containing compounds such as amines, nitrites, and halogenated compounds such as freons.

2.0 LIMITATIONS

The OVA 128 used in the survey mode in unknown atmospheres is strictly quantitative with the reading equivalent to methane. Due to this extreme sensitivity to methane, the unit is limited in any atmosphere that has toxic vapors mixed in with methane. This is why an OVA is not a practical instrument to use on a landfill, if you are looking for toxic vapors.

Moisture is still another limiting factor. The OVA model 128 cannot sample water directly, or any application which may force water vapors into the sample line. Too much water will damage the sample loop, as well as all the in line particle filters, and burner chamber.

The performance includes:

- Readout: 3 ranges 0 to 10, 0 to 100, 0 to 1000 ppm (linear)
- Sample Flow Rate: 1 1/2 to 2 1/2 liters per minute at 22°C
- Response Time: Approximately 2 seconds for 90% of final reading
- Minimal Detectable Limit: 0.2 ppm

3.0 PROCEDURES

3.1 Operations

1) Attach the probe to the main instrument package being careful to properly line-up the electronic jack and sample line to the side pack assembly. Only hand tighten the 1/8 inch sample line nut onto the unit. Move the pump switch to on, and check the battery condition by moving the instrument switch to the battery check position. The needle should deflect past the white line on the probe. If it does not, do not use the instrument. Place the unit on charge.

2) Move the instrument switch to on and allow 2 minutes to warm up.

3) Move the pump switch to the on position and then place the instrument panel in the vertical position. Check the sample flow rate to be sure its 1 1/2 to 2 1/2 LPM.

4) Set the calibrate switch to X1 position and use the calibrate knob and set the meter to read 0 or 1 ppm.

5) Open the hydrogen tank valve all the way, and the hydrogen supply valve 1 and 1/2 turns. The hydrogen supply valve gauge should read between 8 and 12 psi. A full tank of hydrogen (approximately 2000 psi on the tank supply), should last at least 8 hours.

6) After one minute, depress the igniter button until the burner lights. This is indicated by a positive deflection of the meter and a slight popping sound. The meter will slowly come down if unit is lit. Do not depress the igniter button for more than six seconds. If the flame does not light, which is indicated by a slowly rising positive deflection of the meter, wait for one minute and try again.

7) After the detectors flame is lit, use the calibrate knob to zero out the ambient background. For maximum sensitivity below 10ppm, set the calibrate switch to X1 and readjust the zero on the meter. To avoid a false flame-out alarm indication, set the meter to 1ppm with the calibrate knob, and make differential readings from there.

8) When using the OVA in the survey mode, ensure that the sample inject valve remains in the full "out" position and that the backflush valve is either full "in" or full "out". This is only for OVA 128 equipped with the GC accessory.

9) Health and safety reasons, use the OVA on the 0-10ppm range, with the zero established before you enter the site area. Switch to higher ranges as conditions dictate. While taking care not to permit the OVA to be exposed to excessive moisture, dirt, or other contamination, monitor the work as specified in the site Health and Safety Plan. At the end of the day, clean the outside of the instrument with a damp disposable towel.

3.2 Shut-down

1) Close the hydrogen supply valve and the hydrogen tank valve. Do not overtighten these valves, they are easily damaged.

2) Move the instrument switch to off.

3) Wait a few seconds and then move pump switch to off. The instrument is now in a shut down configuration.

4) If possible, immediately place the instrument on charge.

3.3 Hydrogen Refilling

The OVA 128 is filled with Hydrogen prior to being issued from the equipment room. Should on-site H_2 filling be required, the following steps should be taken.

1) In a well ventilated area, away from any source of flame or spark, attach the hydrogen filling hose securely to a cylinder of extra dry hydrogen (less than 2ppm total hydrocarbons).

2) Attach the filling hose to the instrument fill connection and turn on the hydrogen valve making sure the other end of hose is set on off.

3) Turn the fill/bleed valve slowly to bleed and purge the hose for ten seconds.

4) Turn the fill/bleed valve to the close position. Open the refill valve on the instrument and turn the fill/bleed valve to fill.

5) Close the refill valve on the instrument. Close the fill/bleed valve, then close the hydrogen tank valve.

6) Bleed the filling hose completely and disconnect it from the instrument, and the hydrogen tank.

SOP-IN-003
COMBUSTIBLE GAS INDICATOR

1.0 INTRODUCTION

The combustible gas indicator (CGI) is used to determine the concentration of flammable vapors, gases and atmospheric oxygen/deficiency. This information issued to assess explosive potential, and the presence of asphyxiant gases/vapors. The reading is quantitative only.

The CGI can detect and indicate gas concentrations up to the lower explosive limit, and actuate a characteristic audible signal if concentration exceeds a present level. Simultaneously, the unit will analyze for oxygen over a range of 0 to 25% and actuates a different audible signal if O_2 concentration drops below a present level.

The Model 1314 utilizes two detectors. For combustible gas, the combustible components are burned on the platinum filament. This raises the temperature and the electrical resistance of the filament. The decreased electrical current is measured by a potentiometer, which is translated into a reading on the instrument. For O_2, the oxygen in the sample reacts with an electrolyte in the detector cell, generating an electrical current. Another potentiometer translates the increased current into a meter reading. Combustible gas is measured in 0-100% of the LEL (Lower Explosion Limit), while oxygen is measured in percent.

2.0 LIMITATIONS

The limitations for the combustible gas detector are:

- Volatile heavy metals i.e., tetraethyl lead
- High humidity
- Selenium, silicon, and arsenic

For the oxygen detector, these limitations are:

- Temperature and pressure
- Oxidizers (cause elevated readings)
- CO_2 (reduces sensor sensitivity/shortens sensor life)

3.0 PROCEDURES

1) Insert hose coupling into fitting on front of instrument.

2) In an area known to be free of combustible gas, push the instrument power button in the meter will rise upscale and a pulsing alarm will sound. Allow the instrument to warm up 2 minutes.

3) Keep the LEL button and O_2 button in the OUT position.

4) On the instrument panel (on side), turn the PPM/LEL zero knob to adjust the needle to read zero.

5) With both buttons on the instrument panel out, you are monitoring LEL.

6) Press BATT CK button and note meter reading. If reading is close to or below BATT CHECK mark on meter, recharge batteries.

7) Put OXY/LEL switch in the OXY (IN) position, so that orange indicator shows. Turn OXY CAL knob to bring meter to the O_2 CAL mark (21%).

8) As a quick check, allow the instrument to sample expired air, by holding hose inlet loosely between the teeth while breathing out through the mouth. The reading should come down to about 16, and alarm should sound at 19%. Allow it to return to 21, then put switch back in LEL position. Instrument will automatically test for oxygen, whenever it is used, and will give pulsed audible and amber light alarm if oxygen content drops to 19.5%. It is not necessary to use the instrument with the switch in the OXY position unless oxygen measurements are of primary interest. If both abnormal gas conditions exist simultaneously, both lights will blink in their normal pattern, but the buzzer will sound continuously.

9) For reading in the 0-100% LEL range, hold hose inlet at the point to be monitored. Watch the meter and record any readings.

10) Monitor the work activity as specified in the site Health and Safety Plan (HSP).

SOP-IN-004
RADIATION SURVEY METER

1.0 INTRODUCTION

Radioactivity is the property of the nucleus of an atom to spontaneously emit energy in the form of radiation. Excessive nuclear energy emitted in the form of high energy electromagnetic waves or particles, is radiation.

Nuclear radiation is a process that accompanies the transformation of atoms from unstable to stable states. Alpha, beta, and gamma radiation are the three main hazards of concern:

- Alpha particles - Particles consisting of two protons and two neutrons bound together with an electrical charge of +2. Identical to helium nuclei. Through emission of an alpha particle, uranium becomes thorium, and radium becomes radon.

- Beta particles - Particles with a single electrical charge. When negatively charge, identical to electrons.

- Gamma rays - High energy, short wavelength electromagnetic radiation. Other types of electromagnetic radiation includes visible light, ultraviolet, and radar.

The various types of radiation differ in their ability to penetrate matter. The energy of radiation (1 MeV) is as follows:

Type of Radiation	Distance Traveled in Air	Ion-Pairs in 1 cm of Air	Shielding Required
Alpha	Less than 1 inch	Hundreds of thousands	A sheet of paper
Beta	Inches	Hundreds	1/16 inch of aluminum foil
Gamma	Hundreds of feet	1-2	2 feet of aluminum foil

2.0 METER TYPES

CDM utilizes radiation survey meters to determine the presence and levels of radiation. The information gathered is used to establish control measures to reduce or prevent exposure. The Ludlum Model 3 is a waterproof, portable survey instrument that operates on two standard "D" cell flashlight batteries. The instrument features a regulated high-voltage. The power supply is adjustable from 400 to 1500 volts and provides a 4-linear range from 0-200 MR/Hr (the scale multiples are X0.1, X1, X10, X100).

The Ludlum Model 3 is factory calibrated annually. CDM equipment room offers three probes for use with the Ludlum Model 3. The probes are a thin wall Geiger-Mueller Probe, Pancale Geiger-Mueller Probe and an Alpha Scintillation Probe. Contact the CDM equipment room prior to going out on site in order to attain the proper probe for your application.

3.0 PROCEDURE

Specific operating procedures for the Model 3 are as follows:

1) In order to obtain appropriate background readings, the unit should be checked out and switched on approximately 1 mile before entering the suspected site area.

2) Attach the probe cable to both the probe and the unit by turning the BNC connector on either end.

3) Rotate the selector switch to BAT position. (If needle does not reach the proper location, replace the 2 D cell batteries inside.)

4) Rotate selector switch to scale, and select the appropriate range.

5) Turn audio switch on or off as desired.

6) Set F/S switch to fast or slow needle response.

7) Monitor the site following the site Health and Safety Plan (HSP).

8) Turn the instrument off when not in use.

SOP-IN-005
DRAEGER PUMP

1.0 INTRODUCTION

The Model 31 bellows pump is designed together with the proper detection tube, to offer quick and accurate evaluation of hazardous situations. This gas detection system enables the user to make a methodical determination of the particular gases, or vapors present, as well as concentration levels of the contaminants.

This hand held pump draws 100 cubic centimeters of sample gas through a detector tube with each pump stroke. The mode of operation is that of a dosage pump as it carries out both the suction process and volume measurement simultaneously.

If the specific contaminant is known, the proper draeger tube can be purchased for the job. The CDM equipment room will have all the information needed regarding Draeger tube selection. Draeger supplies most all of the sampling tubes we use in the hazardous waste field.

The potential problems which contribute to poor accuracy are:

- Leak in the pump
- Insufficient pump strokes/operator error
- High humidity/temperature
- Interferences from other compounds
- Improperly stored tubes
- Tubes which expired stamp date

Be aware of approximate sample concentrations at the specific location that will be monitored. Order the Draeger tube which sufficiently covers the range of concentration making sure to keep within the range you pick without compromising sensitivity.

2.0 PROCEDURE

1) Break off both ends of the Draeger tube on the breakoff eyelet located on the front cover plate.

2) Insert the opened tube into the pump head with the arrow on the tube pointing towards the pump.

3) Hold the pump in your hand with the holding plate between the thumb and the base of the index finger, and the front cover plate contacting the fingers.

4) Compress the bellows completely with a squeezing motion, assuring that the total volume of the bellows is used.

5) Release the grip and allow the bellows to expand until the chain is taught.

6) Complete steps D and E as many times as the indicator tube instructions state.

7) Look at the tube when completed step F and record the results immediately.

8) Complete steps D and E as many times as the indicator tube instructions state.

SOP-IN-006
PARTICULATE MONITOR

1.0 INTRODUCTION

Aerosol Monitors are used in order to determine the relative concentrations of airborne particulates which may cause a respiratory hazard, such as dusts, fumes, smokes, and fogs. The information gathered by this equipment is used to establish levels of protection, and other control measures such as action levels.

CDM has a Model PDM-3 miniature real-time aerosol monitor. This unit uses a pulsed gallium arsenide light emitting diode source. The radiation scattered by airborne particles is sensed by a silicon-photovoltaic hybrid detector. A filter is incorporated to screen out any light whose wavelength differs from that of the pulsed source. The instrument continuously senses the combined scattering from the population of particles present within its sensing volume (approximately 1 cubic cm). These dimensions are large compared with the average separation between the individual airborne particles.

Air surrounding the PDM-3 passes freely through the open aerosol sensing chamber as a result of air transport caused by convection, circulation, ventilation and personnel motion. No pump is required for this operation. The sensor ranges particle sizes from 0.1 to 10 micrometers. The following controls are located on the front of the miniram PDM-3 as well as their individual functions:

MEAS - Starts the monitoring operation. Instrument will run up to 8.3 hours and will then shut down.

OFF - Stops any operation the instrument was performing.

TIME - Displays the elapsed time from the start of the measurement run. When pressed at the same time as the MEAS control, the instrument will operate continuously and <u>will not</u> automatically shut down.

TWA - Displays the time Weighted Average concentration in mg/cm^3 since the start of the run.

SA - Displays an 8 hour TWA.

PBK - With the instrument in the OFF mode, displays its stored data. If pressed for less than one second, the information will relayed through the digital output jack for printout.

ZERO - While operating, displays the stored zero value. To rezero the instrument, press OFF and the press ZERO. The next four consecutive ten second measurements are average and stored as the zero reference value. Wait until the display reads OFF before continuing measurements.

ID - Displays the instrument identification number.

The instrument is factory calibrated once a year against a filter gravimetric reference, using a standard test dust (Arizona road dust).

2.0 PROCEDURE

1) In a known dust free area, press OFF.

2) Depress zero and wait for the display to read OFF.

3) If the display is blank, press OFF and wait for the display to read OFF.

4) Press MEAS to begin measurement cycle. The first reading displayed will be GO followed by the last reading or 0.0.

5) After 36 seconds, the first new 10 second-average reading will be displayed.

6) Readings of 0.00 to 9.99 milligrams per cubic meter range. (If the ten second average exceeds 9.99 milligrams/cubic meter the LCD display will shift to range 0.0 to 99.9 milligrams per cubic meter.

7) Monitor the work activity as specified in the CA/T Site Health and Safety Plan.

8) The reading displayed on the instrument is updated every ten seconds.

9) At the end of the activity or day, press OFF.

There are 3 bar indicators on the face of the PDM-3, identified as OVR, ID and Batt. If the OVR bar is displayed at any time during operation in the measurement mode, the detection circuit is overloaded. This is caused by an object being inserted into the sensing chamber or sudden exposure to the chamber by sunlight. If either problem is eliminated, the bar will disappear during the next 10 second display period (If the problem is fixed in <1.5 minutes). If not, the OVR bar will remain on for the remainder of the run. This can be corrected by turning the unit off and wait 5 minutes ensuring all the conditions are correct, then press MEAS. A normal cycle should then occur, if not, bring the unit back to the CDM equipment warehouse. Always keep the instrument in its protective case when not being used and charge the instrument after use.

Other error codes include:

- 01: low battery condition
- 02: RAM (digital processing)
- 03: A/D (signal) overload

SOP-IN-007
AIR SAMPLING PUMP

1.0 INTRODUCTION

The purpose of a detailed air quality survey is to qualitatively and quantitatively examine the chemical composition of the vapors, gases, and particulates being released into the environment. The utilization of direct reading instrumentation during the walk-over survey provides some information regarding the presence of a hazardous emissions at the site. However, these field instruments are in general not "specific" for individual hazardous substances and therefore provide little information regarding the actual chemical composition of the airborne emissions at the waste site.

The identification of chemical specific hazardous emissions can only be completed through a program comprised of field collection, and subsequent laboratory analysis of individual samples. Samples are collected at known flow rates for a specified time interval and this information is combined with the laboratory analysis to establish the ambient air concentrations for individual hazardous materials.

CDM uses an SKC series 224 sampling pump to monitor ambient air through specific detector tubes. These pumps are set up to operate in the breathing zone in order to monitor for Health & Safety protocol. The series 224 sampling pump is a dual diaphragm design, driven by a high efficiency DC motor. The diaphragm pump is combined with special low pressure, positive acting values. The pump mechanism is sealed to prevent dirt from entering. The DC motor operates from rechargeable NiCd batteries.

The flow system is controlled to give an even, constant flow. This flow rate is maintained even if back pressure increases. Should the pump flow become obstructed, the unit will automatically shut itself down. When pump shutdown occurs, a fault light is displayed as well as the time the shutdown occurred.

Before calibration is performed, a specific detector tube filter should be chosen to collect the required sample. Along with this, a specific flow rate will be needed as well as a sampling period. This information can be obtained from the laboratory performing the analysis.

After the pump is calibrated to required specifications, it is ready for operation.

2.0 PROCEDURE

1) Charge the unit for a minimum of 12 hours prior to use.

2) Connect the sample tube, or filter to the tube leading to the pump.

3) With the pump off, use a small screwdriver to set the timers. The left dial set 100 minute increments, and the right dial sets 10 minute increments. For example, if the operator desires the pump to operate for 8 hours, it should be set for 480 minutes. Set the left dial at 4 and the right dial at 8. (Note: If the timer has not been used for some time, rotate the dial several times to clear the contacts. If you are not going to use the timer, set the left dial to 9.

4) When the set time is reached, the pump will shut down. Pressing the "Press-to-Test" button will indicate the exact running time.

5) Turn on the pump. Remember never to set the timer while the pump is operating or else the "Time Out" will occur at the previous setting.

6) Press the "Press-to-Test" button to determine the battery charge condition. The light should light or flicker indicating a full charge.

7) After the pump has shut down, verify that the required amount of minutes have been run (Press-to-Test" button)

8) Remove the tube or filter from the end of the sample line and cap both ends.

SOP-IN-008
DISSOLVED OXYGEN METER

1.0 INTRODUCTION

The dissolved oxygen meter is used to give continuous DO readings in water, wastewater, and certain other liquids. The DO probe uses a polarographic sensor with built in thermistors for temperature measurement, and compensation. A thin, permeable membrane stretched over the sensor isolates the sensor elements from the environment but allows oxygen to enter. When voltage is applied across the sensor, oxygen that has passed through the membrane reacts at the cathode causing a current to flow. The membrane passes oxygen at a rate proportional to the pressure difference across it. Since oxygen is rapidly consumed at the cathode, it can be assumed that the oxygen pressure inside the membrane is zero. Hence, the force causing the oxygen to diffuse through the membrane is proportional to the absolute pressure of oxygen outside the membrane. If the oxygen pressure increases, more oxygen diffuses through the membrane, and more current flows through the sensor. A lower pressure results in less current.

Limiting factors includes dissolved organic material and dissolved inorganic salts, which interfere in the DO probe output. Reactive type compounds such as H_2S and chlorine interfere with the probe.

2.0 CALIBRATION

All DO meters should be calibrated in the field using the following procedures:

1) Attach the probe to the face of the instrument (line up groove and tighten).

2) Turn on the instrument and allow 15 minute warm-up period to ensure probe stabilization.

3) Keep the probe tip in the plastic container that covers the membrane assembly. This chamber is moist and assumes 100% humidity. Ensure that this cap has moist clean kimwipes inside of it, and that the membrane is not placed in direct contact with the moist paper.

4) Zero the instrument by using the zero knob on the front of the meter.

5) Switch to TEMPERATURE and read. Refer to the chart on the back of the YSI meter.

6) Determine the altitude you're working in and check on the table on the back of the YSI for corresponding correction factor.

7) Multiply (if necessary) the calibration value by the correction factor. Write down this number.

8) Switch the unit to the appropriate mg/l range. The DO range goes 0-5, 0-10, 0-20 mg/l. Set the salinity knob to zero and adjust the CALIBRATE knob until the meter reads the correct value determined in step E. Wait 2 minutes to verify the correct setting.

9) The probe is calibrated and ready to use.

3.0 PROCEDURE

With the DO meter calibrated, remove the plastic cover on the tip of the probe. Place the probe in the sample and slowly raise and lower it in the sample. Adjust the salinity knob to the salinity of the sample. Allow about two minutes for the probe to stabilize to sample temperature and dissolved oxygen, and read the dissolved oxygen level.

If the DO probe has torn or damaged membrane, return it to the CDM equipment room where a new probe will be issued. Air bubbles can form under the membrane, check daily for this occurrence. The membrane, if bubbles are found, should be replaced.

If the DO meter is being used, an extended amount of time, the user can take spare membranes and filling solution to the site. The DO manual has a step by step instruction on the replacement of DO membranes.

SOP-IN-009
pH METER

1.0 INTRODUCTION

pH is the negative logarithm of the effective hydrogen ion concentration (or activity) in gram equivalents per liter used. This expresses both acidity, and alkalinity on a scale whose valves run from 0 to 14. Number 7 represents neutrality, and numbers greater than 7 indicate increasing alkalinity while numbers less than 7 indicate increasing acidity. pH is one of the most commonly analyzed parameters. Water supply treatment such as neutralization, softening, disinfection and corrosion control are all pH dependent. CDM has a variety of pH monitoring instruments in the equipment warehouse.

2.0 ORION SA 250 pH PROCEDURES

With the instrument fully calibrated, it is now ready for use. Follow the check out procedures:

1) Slide power switch to on position. Attach BNC shorting plug to BNC connector on top of meter.

2) If LO BAT indicator on LCD remains on, the battery must be replaced.

3) Slide mode switch to mv. Display should read $0 \pm .3$.

4) Slide mode switch to TEMP. Display should red 25.0. If 25.0 is not displayed, scroll using, and X10 keys, until 25.0 is displayed and press enter.

5) Slide mode switch to pH .01. Press iso. Display should read the letters ISO, then a value of 7.000. If 7.000 is not displayed, scroll until 7.00 is displayed and press enter.

6) Press slope. Display should read the letters SLP, then a value of 100.0. If 100.0 is not displayed, scroll until 100.0 is displayed and press enter.

7) Press sample. Observe the letters pH, then a steady reading of 7.00, $\pm$0.02 should be obtained. If not, press CAL and scroll until 200 is displayed and press enter. Press sample and observe a reading of 7.00.

8) Remove the shorting plug. After completing these steps, the meter is ready to use with an electrode.

9) Attach electrodes with BNC connectors to sensor input by sliding the connector onto the input, pushing down and turning clockwise to lock into position. Connect reference electrodes with pin tip connectors by pushing connector straight into reference input.

10) Put the temperature probe in the sample and let it stabilize.

11) Once temperature is stable, set the unit to read pH (by 0.1 or 0.01) and take a reading in the aqueous sample. (Remembering first to remove the cap on the end of the pH probe.)

3.0 MODEL TRIPAR ANALYZER PROCEDURES

With the instrument fully calibrated, it is now ready for use:

1) Connect the pH probe's BNC input connector to the front of the Tripar.
2) Put the pH/mv switch on the pH position.
3) Turn the parameter display selection switch to TEMP.
4) Plug in the gray temperature plug jack in the input temperature sensor connector.
5) Put end of temperature probe in the sample.
6) Allow the temperature to stabilize.
7) Turn the temperature compensation knob to the temperature shown.
8) Turn the parameter display selection switch to pH.
9) Put pH probe in the aqueous sample (remembering first to remove the cap on the end of the probe). Let it stabilize and record the reading.

SOP-IN-010
CONDUCTIVITY METER

1.0 INTRODUCTION

Conductivity is a numerical expression of the ability of an aqueous solution to carry an electrical current. This ability depends on the presence of ions in the solution, and their total concentration. Factors such as mobility valence, relative concentration, and temperature also combine to create this occurrence. Solutions of most inorganic acids, bases and salts are relatively good conductors. Organic compounds in aqueous solutions are not good conductors. For example, freshly distilled water has conductivity reading of .5 to 2 mhos/cm and increases with time. This increase is caused by absorption of atmospheric carbon dioxide, and to a lesser extent ammonia. While industrial type wastes have conductivity readings of 10,000 $\pm$mhos/cm.

2.0 MODEL SCT PROCEDURES

The model 33 SCT has 3 conductivity scales of 0-500, 0-5000, and 0-50,000 mhos/cm. Salinity is scaled 0-40 parts per thousand in a temperature range of -2 to +45°C. Temperature is scaled -2° to +5°C.

With the instruments calibration verified, the unit is now ready for use. The model 33 S-C-T meter face is scaled and calibrated to give an accurate reading of the conductivity of a water sample by measuring the amount of current flow between two fixed electrodes in the probe. The unit also measures salinity in a special range conductivity circuit, which includes a user-adjusted temperature compensator. A precision thermistor in the probe measures temperature by changing its resistance in relation to the temperature of the water.

The start-up procedure is as follows:

1) Plug the probe plug receptacle in the side of the meter.

2) With the mode select in the OFF position, check to see that the meter needle is centered at the zero mark on the conductivity scale and adjust if necessary.

3) Turn the mode control switch to Red Line position.

4) Adjust the Red Line control knob so the meter needle lines up with the red line on the meter face. If this cannot be accomplished, replace the batteries. If battery replacement is necessary, use only alkaline "D" cells as regular carbon zinc batteries will cause errors.

5) Place the probe into the solution to be measured.

6) Set the mode control to TEMPERATURE. Read the temperature on the bottom scale of the meter in °C. Allow time for the probe temperature to come to equilibrium before taking a reading.

7) With the probe in the solution to be tested, adjust the conductivity scale until the meter reading is on scale. (Multiply the reading by the correction on the calibration sticker on the instrument).

8) When using the X10 and X100 scales, depress the CELL TEST button. If the reading on the dial moves $\pm$2%, the electrode is fouled and needs to be cleaned. Repeat the measurement on another instrument.

9) Store the probe in distilled water when not in use.

SOP-IN-011
PHOTOVAC PORTABLE GAS CHROMATOGRAPH

1.0 INTRODUCTION

The Photovac portable gas chromatograph (GC) can provide for accurate and specific identification of volatile organic compounds in a field control laboratory.

2.0 EQUIPMENT PREPARATION

1) The Photovac portable gas chromatograph should be set up in a sheltered area and, if possible, within a climate controlled area to minimize temperature changes. Do not place the GC near any equipment that causes vibration. A flat table, large enough to accommodate the GC, the printer, a lab size oven, and electrical power packs for the GC should be utilized during operation.

2) Fill the GC with carrier gas being sure not to pressurize the GC with more than 1500 psi of carrier gas. Check to ensure the pressure of the air feed to the GC column is 40 psi. The carrier gas should contain no more than 2.0 ppmv of total hydrocarbons and not less than 0.1 ppmv of total hydrocarbons. The lower the hydrocarbon concentration the lower the baseline of the GC. A lower baseline minimizes interference of compound identification.

3) Install a new Teflon septa in the injection port being utilized. The septa should be replaced at the start of each day and after every twenty injections.

3.0 CALIBRATION PROCEDURES AND FREQUENCY

The Photovac portable gas chromatograph will be calibrated at the beginning of each day prior to sample analysis.

- Gas Standards

  Gas standards used to calibrate the GC will be obtained from certified compressed gas cylinders of known concentration. CDM stocks two compressed gas standard cylinders containing the following gases and concentrations:

- Cylinder 1

  Benzene - 10 ppmv
  Toluene - 10 ppmv
  Ethyl Benzene - 10 ppmv
  M-xylene - 10 ppmv
  O-xylene - 10 ppmv
  P-xylene - 10 ppmv

- Cylinder 2

  Trans 1,2 Dichloroethylene - 1.05 ppmv
  1,1,1 Trichloroethane - 19.3 ppmv
  Trichloroethylene - 1.13 ppmv

These gas cylinders were purchased from Scott Specialty Gas Corporation and are certified by Scott to be traceable to NBS standards.

The calibration procedure using these cylinders is as follows:

1) A two stage pressure regulator (CGA 350) is attached to the standard gas cylinder to be used.

2) A 250 ml glass sampling bulb, determined clean by injecting a volume of air obtained from the bulb onto the GC (described later), is labeled and attached to the effluent port of the second stage of the gas regulator. The Teflon stopcocks of the sampling bulb are opened.

3) The sample cylinder valve is opened and the first stage of the regulator is pressurized.

4) Slowly the diaphragm valve controlling the gas flow entering the second stage is opened until the pressure reads 2 psig.

5) The valve allowing the gas to exit the second stage of the regulator is opened until the gas can be heard escaping from the regulator and passing through the glass sample bulb. Purge the bulb for approximately ten seconds. Close the Teflon stopcock located at the discharge end of the sampling bulb, then, the stopcock closest to the regulator. In this way the calibration gas is collected at the same pressure as the delivery pressure of the second stage of the regulator.

6) Using a gas tight 1 ml syringe, extract approximately 500 ul of the calibration gas from the glass bulb and purge the volume of gas into the atmosphere. Repeat this step.

7) Place the syringe needle in the glass bulb. Pull the syringe plunger back so approximately 500 ul of calibration gas enters the syringe barrel. Without removing the syringe from the glass bulb depress the plunger. Pump the syringe in this manner several times.

8) Extract the syringe from the glass bulb with approximately 500 ul of calibration gas present. Carefully depress the plunger until 300 ul of calibration gas is present in the syringe barrel. Immediately inject this gas volume into the Photovac gas chromatograph.

9) A response factor for each analyte is obtained as the ratio of the known gas concentration injected and the area under the peak produced by that injection. This integration is performed automatically by the internal Photovac data processor and stored in the library.

10) The procedure to obtain a calibration gas sample is repeated and the gas volume is injected into the GC. The GC will identify the compounds in the sample stream that have retention times within +/- 20% of the retention times of the compounds in the library. The area of these identified peaks will be compared to the response factor of the compounds stored in the library and integrate a corresponding concentration.

11) If the calibration check concentration does not equal +/- 15% of the library concentration, a new calibration check is performed. If this check fails, a new library is created.

4.0 SAMPLE ANALYSES

The following procedure will be followed when performing analysis of samples.

1) The Photovac portable GC is set as described above. The GC function and application file is loaded into memory. This includes all previously established calibration data and retention time information.

2) 300 ul of sample are obtained from the sample source and injected into the GC. Samples will be injected as soon as possible after it is collected.

3) Immediately after injection the GC is started.

4) Each chromatograph run will run for a minimum of 5 minutes. At this time the run will be stopped and the results obtained.

5) Following completion of the run, the Photovac GC will produce a hard copy printout of the results. This printout will include the sample identification, time of analysis, and appropriate operating parameters.

This procedure will be followed for all sample runs.

5.0 METHOD BLANKS AND DUPLICATES

Prior to any calibration or sample injections, the integrity and level of contamination of each syringe used for injections will be verified.

1) Plungers will be removed from the barrel of the syringe and placed into a laboratory oven for 5 minutes. The temperature of the oven should not be above 150 degrees F or below 120 degrees F.

2) The syringes will be removed from the oven, cooled, and reassembled.

3) Pump the syringe plunger several times, purging the syringe with ambient air.

4) Collect approximately 500 ul of ambient air in the syringe and carefully depress the plunger to 300 ul. Immediately inject the gas volume into the GC.

5) Detection of the target compounds above the detection limit (50 ppbv for most compounds) will require another decontamination procedure before additional analyses.

6) Blanks will be performed after every sample and calibration injection. Blanks will not be performed between duplicate sample injections.

7) Duplicate samples will be performed at a minimum of 1 every 10 sample injections.

STANDARD OPERATING PROCEDURES

LABORATORY PROCEDURES

SOP-LA-001
LABORATORY DATA QUALITY ASSESSMENT

1.0 INTRODUCTION

The term "data quality" refers to the level of uncertainty associated with a particular data set. The data quality associated with environmental measurement data is a function of the sampling plan rationale and procedures used to collect the samples as well as the analytical methods and instrumentation used in making the measurements. Each component has its own potential sources of error and biases that can effect the overall measurement process.

Sources of error that can be traced to the sampling component of environmental data collection are poor sampling plan design, inconsistent use of standard operating procedures, sample handling, and transportation. The most common sources of error that can be traced to the analytical component of the total measurement system are calibration and contamination problems. It is recognized that by far the largest component of the total uncertainty associated with environmental data collection originates from the sampling process. All sampling programs initiated in support of this project will stress forward planning and be well conceived and reviewed prior to the collection of any samples as a way to minimize this major source of potential error.

Uncertainty cannot be eliminated from environmental measurement data. The amount of uncertainty that can be tolerated depends on the objective of the sampling program and the intended use of the data collected. The purpose of the project's quality assurance program is to assure that the data quality of all data collected be of known and ascertainable value.

2.0 DATA QUALITY CRITERIA

Data quality will be assessed in terms of its precision, accuracy, representativeness, completeness, and comparability. Although not a data quality parameter per se, analytical method detection limits will also be discussed in this section. Each parameter will now be discussed individually.

2.1 Precision

Precision is a measure of the reproducibility of analyses under a given set of conditions. The overall precision of a sampling event is a mixture of sampling and analytical factors. The precision of data collected in support of this project will be assessed on two different levels:

- by calculating the relative percent difference (RPD) of laboratory matrix spike duplicates and/or laboratory replicate samples (a measure of analytical precision)

- by calculating the RPD of field duplicates samples submitted to laboratory "blind" (a measure of the precision of the entire measurement system, including sampling)

Relative percent difference will be calculated according to the following equation:

$$RPD = \frac{|A - B|}{(A + B)/2} \times 100\%$$

where: A = Sample Result
B = Replicate Sample Result

2.2 Accuracy

Accuracy is a measurement of the amount of bias that exists in a measurement system. This can be thought of as the degree that the reported value agrees with the supposed "true value". The accuracy of data collected in support of this project will be assessed in the following ways:

- by calculating the percent recovery (%R) of laboratory matrix spikes and/or laboratory control standards
- by documenting the level of contamination that exists (if any) in laboratory method blanks
- by documenting the level of contamination that exists (if any) in field and/or trip blanks submitted to the laboratory "blind" for analysis
- Percent recovery will be calculated according to the following equation:

$$\%R = \frac{SSR - SR}{SC} \times 100$$

where: SSR = Spiked Sample Result
SR = Sample Result
SA = Spike Concentration

2.3 Representativeness

Unlike the previous two criteria which can be expressed in quantitative terms, representativeness is a qualitative parameter. However, in terms of overall data quality, representativeness may be the most important parameter of all.

The representativeness criterion is concerned with the degree to which a sample reflects (represents) a characteristic of a population, parameter variations at a specific location or an environmental condition. Sample representativeness will be addressed in support of this project through a detailed sampling plan design and rationale and through the proper use of the appropriate sampling standard operating procedures, depending on sample matrix and the parameters to be analyzed.

Composite samples will be collected in situations conducive to compositing techniques (particularly samples collected along the vertical extent of a borehole). The use of composite samples tends to maximize the representativeness of a sampling round because more information is provided about a much broader area than a single grab sample. This is especially true in situations where the objective of sampling is to determine where gross contamination exits on site and the location of any "hot spots". In these cases, broad coverage of the area to be sampled is more important than obtaining the lowest possible detection limits.

2.4 Completeness

The completeness criterion is a measure of whether all the information necessary for a valid scientific study has been collected. It is evaluated by comparing the project objectives with the amount of data collected to determine if any data "short falls" exist. Missing data can result from many occurrences, from sample acquisition and accessibility problems to sample breakage and data rejected because of quality control deficiencies.

The critical sample concept is important part of the completeness criterion. Critical data points are sample locations for which valid data must be obtained in order for the sampling event to be considered complete. If a sampling location is determined to be a critical data point, it will be denoted as such in the sampling and analytical plan and in the project field logbooks.

2.5 Comparability

The comparability criterion is a quality characteristic which is an expression of the confidence with which one data set can be compared with another. Comparability issues are of importance at two different levels of a sampling program. The primary comparability issues are concerned with whether the field sampling techniques, analytical procedures, and concentration units of one data set can be compared with another.

The comparability criterion also applies to the environmental conditions/ considerations present at the time of the sampling. Temporal and/or seasonal variations may make data collected from the same location at different times of the year incomparable, or comparable in a relative sense only, for example.

Comparability is a prime concern when existing data is being integrated into an on-going project's data base. Special attention will be given in this regard whenever existing data is being used in support of this project.

2.6 Method Detection Limits

Whenever environmental measurement data is to be used in comparison with predetermined "action levels" or other regulatory requirements, the reported method detection limits of the analytical data is of prime importance. Analytical methods specified in support of this project should have a reported detection limit at least 50% below the required action level to assure that measurements made in the vicinity of the action level are of high quality. In circumstances concerning extremely low action levels or regulatory requirements where analytical techniques will have to be pushed to their limits, every effort will be made to select the most appropriate analytical procedures.

It is recognized that analytical detection limits are sample specific and are affected by sample volumes as well as the need for sample concentration or dilution. These circumstances will be accounted for in the review and interpretation of the analytical results.

3.0 QUALITY CONTROL

Two separate levels of quality control exist for all samples collected in support of this project, internal laboratory quality control and program generated quality control.

3.1 Internal Laboratory Quality Control

Internal laboratory quality control is a function of the individual laboratory's Quality Assurance/Quality Control (QA/QC) Plan. A laboratory's QA/QC plan contains specific criteria governing the manner in which analyses are conducted and provide information on the laboratory's performance and control of the sources of error that exist within the lab. Included in the plan are requirements for the type and frequency of quality control check samples that are to be analyzed on a routine basis.

All laboratory analysis conducted in support of this project must include the following quality control check samples:

- Surrogate spikes (where appropriate)
- Matrix spike/matrix spike duplicate or laboratory duplicates and laboratory control samples (where appropriate)
- Method blanks

The laboratory may adhere to the analysis frequency specified in their QA/QC plan for these check samples provided that the specified frequency is equal-to or greater-than the frequency specified in Table 1 or as modified/specified by the QAP.

3.2 Program Generated Quality Control

Program generated quality control consists of quality control check samples that are submitted to the laboratory for analysis "blind" along with actual environmental samples. These samples provide quality control information for the entire sampling event, from the actual sampling and handling through laboratory analysis. As such, they can provide the best overall estimate of the total uncertainty associated with the sampling round.

TABLE 1

LABORATORY SAMPLE FREQUENCY

QC Check Sample	Frequency of Analysis
Method Blanks	One per analytical batch or one per every twenty samples
Matrix Spike/Matrix[1]	One per analytical batch or one per every twenty samples
Spike Duplicate (MS/MSD)	Same
Surrogate Spikes	One per every trace organic analysis

---

[1] The combination of laboratory duplicates and laboratory control samples may be substituted for MS/MSD analysis for parameters where they are more appropriate.

Program generated quality control samples collected in support of this project are:

- Field replicated samples
- Field blanks
- Trip blanks
- Rinsate blanks
- Background samples

Each report should have a cover page that references the CDM task number. The cover page also provides an opportunity to describe in a narrative format any unusual problems or interferences encountered during analysis. In addition, all results should be reported on a dry weight basis for soils and at dilution-corrected concentrations for all samples.

3.2 QC Deliverables Package

The following quality control data is required to be reported. For "priority pollutant" type analysis, the following quality control data is required per sample batch:

- **Method Blanks** associated with each analytical procedure.
- **Surrogate Spike Recoveries** for volatile organics, PCBs, semi-volatiles and polynuclear aromatic hydrocarbons.
- **Matrix Spike/Matrix Spike Duplicates** for all priority pollutant parameters. One MS/MSD should be run for every 20 samples.

For non-priority pollutant parameters, the following quality control data is required per sample batch:

- **Method Blanks**
- **Laboratory Duplicates** -- One duplicate analysis should be performed at a frequency of one per twenty samples.

No specific acceptance criteria for blanks and spike recoveries will be set forth here, however, all labs are expected to conform to standard EPA quality control specifications. CDM expects laboratories to reanalyze samples if quality control samples fail to meet EPA specifications.

The quality control data may be presented as a quality control section within the report or it may be integrated among the results.

3.4 Minimum Detection Limits

Tables 2 to 7 present the water and soil detection limits required for projects. Detection limits for soil were derived based on the amount of soil required for each analysis in EPA SW846 and the projected average moisture content for soils encountered during this project. These soil MDLs are target limits and should be adhered to as closely as possible.

TABLE 2

DETECTION LIMITS FOR VOLATILE ORGANIC COMPOUNDS

Parameter	Matrix: Aqueous (ug/L)	Matrix: Solid (ug/kg dry)
Benzene	1.0	3.0
Bromodichloromethane	1.0	3.0
Bromoform	1.0	3.0
Bromomethane	5.0	15
Carbon tetrachloride	1.0	3.0
Chlorobenzene	1.0	3.0
Chloroethane	5.0	15
2-Chloroethyl vinyl ether	5.0	15
Chloroform	1.0	3.0
Dichloromethane	5.0	15
Dibromochloromethane	1.0	3.0
Dichlorodifluoromethane	1.0	3.0
1,2-Dichlorobenzene(V)	1.0	3.0
1,3-Dichlorobenzene(V)	1.0	3.0
1,4-Dichlorobenzene(V)	1.0	3.0
1,1-Dichloroethane	1.0	3.0
1,2-Dichloroethane	1.0	3.0
1,1-Dichloroethene	1.0	3.0
cis-1,2-Dichloroethene	1.0	3.0
trans-1,2-Dichloroethene	1.0	3.0
1,2-Cichloropropane	1.0	3.0
cis-1,3-Dichloropropene	1.0	3.0
Ethylbenzene	1.0	3.0
Chloromethane	1.0	3.0
1,1,2,2-Tetrachloroethane	1.0	3.0
Tetrachloroethene	1.0	3.0
Toluene	1.0	3.0
1,1,1-Trichloroethane	1.0	3.0
1,1,2-Trichloroethane	1.0	3.0
Trichloroethene	1.0	3.0
Trichlorofluoromethane	1.0	3.0
Vinyl chloride	5.0	15
Carbon disulfide	1.0	3.0
Acetone	2.0	6.0
vinyl acetate	2.0	6.0
Methyl ethyl ketone	2.0	6.0

TABLE 2

DETECTION LIMITS FOR VOLATILE ORGANIC COMPOUNDS (Continued)

Parameter	Matrix: Aqueous (ug/L)	Matrix: Solid (ug/kg dry)
Isopropylacetone	2.0	6.0
2-Hexanone	2.0	6.0
Styrene	1.0	3.0
Xylenes	1.0	3.0

Notes:

(1) Reporting limits expressed refer to a "best case" scenario. High target and non-target concentrations may require analytical dilutions resulting in elevated reporting limits.

(2) Detection limits for solid matrices (soils, sludges) based on sample aliquot size specified by method with approximately 25% moisture content. Matrix interferences and high moisture soils may result in elevated reporting limits.

TABLE 3

DETECTION LIMITS FOR SEMI-VOLATILE ORGANIC COMPOUNDS

Parameter	Matrix: Aqueous (ug/L)	Matrix: Solid (ug/kg dry)
Aniline	10	300
Benzyl alcohol	20	600
Bis(2-chloroethyl)ether	10	300
Bis(2-chloroisopropyl)ether	10	300
2-Chlorophenol	10	300
1,3-Dichlorobenzene(A)	10	300
1,4-Dichlorobenzene(A)	10	300
1,2-Dichlorobenzene(A)	10	300
Hexachloroethane	10	300
2-Methyl phenol	10	300
4-Methyl phenol	10	300
N-Nitrosodimethylamine	10	300
N-Nitrosodi-N-propylamine	10	300
Phenols	10	300
Benzoic acid	50	1500
Bis(w-chloroethoxy)methane	10	300
4-chloroaniline	10	300
4-Chloro-3-methylphenol	10	300
2-4-Dichlorophenol	10	300
2,4-Dimethylphenol	10	300
Hexachlorobutadiene	10	300
Isophorone	10	300
2-Methylnaphthalene	10	300
Naphthalene	10	300
Nitrobenzene	10	300
1,2,4-Trichlorobenzene	10	300
Acenaphthene	10	300
Acenaphthylene	10	300
2-Chloronaphthalene	10	300
4-Chlorophenyl phenyl ether	10	300
Dibenzofuran	10	300
Diethyl phthalate	10	300
Dimethyl phthalate	10	300
2,4-Dinitrophenol	50	1500

Notes:

(1) Reporting limits expressed refer to a "best case" scenario. High target and non-target concentrations may require analytical dilutions resulting in elevated reporting limits.

(2) Detection limits for solid matrices (soils, sludges) based on sample aliquot size specified by method with approximately 25% moisture content. Matrix interferences and high moisture soils may result in elevated reporting limits.

TABLE 4

DETECTION LIMITS FOR ABN-EXTRACTABLE ORGANICS

Parameter	Matrix: Aqueous (ug/L)	Matrix: Solid (ug/kg dry)
2,4-Dinitrotoluene	10	300
2,6-Dinitrotoluene	10	300
Fluorene	10	300
Hexachlorocyclopentadiene	10	300
2-Nitroanaline	50	1500
3-Nitroaniline	50	1500
4-Nitroaniline	50	1500
4-Nitrophenol	50	1500
2,4,6-Trichlorophenol	10	300
2,4,5-Trichlorophenol	10	300
Anthracene	10	300
4-Bromophynyl phenyl ether	10	300
Di-n-butyl phenyl ether	10	300
Di-n-butyl phthalate	10	300
2-Methyl-4,6-dinitrophenol	10	300
diphenylhydrazines	10	300
Fluoranthene	10	300
Hexachlorobenzene	10	300
N-Nitrosodiphenylamines	10	300
Pentachlorophenol	50	1500
Phenanthrene	10	300

Benzo(a)anthracene	10	300
Di(2-ethylhexyl)phthalate (DEHP)	10	300
Butyl benzyl phthalate	10	300
Chrysene	10	300
3,3'-Dichlorobenzidene	20	600
Pyrene	10	300
Benzo(b)fluoranthene	10	300
Benzo(k)fluoranthene	10	300
Benzo(ghi)pyrene	10	300
Dibenzo(a,h)anthracene	10	300
Di-n-octyl phthalate	10	300
Indeno(1,2,3,-c,d)pyrene	10	300

Notes:

(1) Reporting limits expressed refer to a "best case" scenario. High target and non-target concentrations may require analytical dilutions resulting in elevated reporting limits.

(2) Detection limits for solid matrices (soils, sludges) based on sample aliquot size specified by method with approximately 25% moisture content. Matrix interferences and high moisture soils may result in elevated reporting limits.

TABLE 5

DETECTION LIMITS FOR PCBs

Parameter	Matrix: Aqueous (ug/L)	Matrix: Solid (ug/kg dry)
Aroclor 1221	0.5	0.05
Aroclor 1232	0.5	0.05
Aroclor 1242/1016	0.5	0.05
Aroclor 1248	0.5	0.05
Aroclor 1254	0.5	0.05
Aroclor 1260	0.5	0.05

Notes:

(1) Reporting limits expressed refer to a "best case" scenario. High target and non-target concentrations may require analytical dilutions resulting in elevated reporting limits.

(2) Detection limits for solid matrices (soils, sludges) based on sample aliquot size specified by method with approximately 25% moisture content. Matrix interferences and high moisture soils may result in elevated reporting limits.

TABLE 6

DETECTION LIMITS FOR PESTICIDES

Parameter	Matrix: Aqueous (ug/L)	Matrix: Solid (ug/kg dry)
Methoxychlor	0.2	0.02
Chlordane	0.5	0.50
Toxaphene	1.0	0.10

Notes:

(1) Reporting limits expressed refer to a "best case" scenario. High target and non-target concentrations may require analytical dilutions resulting in elevated reporting limits.

(2) Detection limits for solid matrices (soils, sludges) based on sample aliquot size specified by method with approximately 25% moisture content. Matrix interferences and high moisture soils may result in elevated reporting limits.

TABLE 7

DETECTION LIMITS FOR TRACE METALS

Parameter	Matrix: Aqueous (ug/L)	Matrix: Solid (ug/kg dry)
Antimony	60	6.0
Arsenic	5	0.5
Beryllium	10	1.0
Cadmium	10	1.0
Chromium	20	2.0
Copper	20	2.0
Lead	50	5.0
Mercury	0.5	0.3
Nickel	20	2.0
Selenium	10	1.0
Silver	20	2.0
Thallium	75	10
Zinc	20	2.0

Notes:

(1) Reporting limits expressed refer to a "best case" scenario. High target and non-target concentrations may require analytical dilutions resulting in elevated reporting limits.

(2) Detection limits for solid matrices (soils, sludges) based on sample aliquot size specified by method with approximately 25% moisture content. Matrix interferences and high moisture soils may result in elevated reporting limits.

4.0 DATA QUALITY REQUIREMENTS

Taking into consideration a project's overall objective and intended use of the data, it should be considered that analyses be conducted in accordance with SW-846, Test Methods for Evaluating Solid Waste, Third Edition procedures. In cases where additional procedures are required, other EPA approved laboratory methods will be used. The specific method reference for a given sampling round will be provided in the site specific SAP or QAP. The precision goals for field duplicates, accuracy goals for laboratory matrix spikes and/or laboratory control samples and completeness goals will also be specified in the SAP or QAP.

Appendix B

RIDEM Guidelines
for the
Management of Investigative Derived Waste

State of Rhode Island
Department of Environmental Management
Division of Site Remediation

Policy Memo 95-01

Guidelines for the Management of Investigation Derived Wastes

1.0 Purpose

The purpose of this policy memo is to provide guidance regarding the management of potentially contaminated materials generated during environmental site investigations, pilot tests, and interim remedial actions (hereafter referred to as investigatory activities) conducted on property in Rhode Island. It is the intent of the Department that the management of investigation derived wastes (IDW) be:

- protective of human health and the environment, and accordingly result in no additional site related risks than existed prior to investigation activities;
- cost effective, consider the likely site remedy and consider waste minimization techniques; and
- done in a manner consistent with all applicable or relevant and appropriate requirements to the extent practicable.

The management of IDW should recognize that investigatory activities are not considered comprehensive remedial actions, and therefore final management of most materials encountered during these activities should be postponed to the extent feasible until a final site remedy has been determined.

The potential problems of managing IDW should be a factor in choosing an investigative method. Project managers should strive to minimize the generation of IDW to reduce the need for special storage or disposal requirements that may result in substantial additional costs yet provide little or no reduction in site risks relative to the final remedial actions.

It is important to note that for all investigatory activities in areas which have the potential to encounter a listed hazardous waste stream, all IDW originating from the area of concern must be managed in accordance with the Department's Rules and Regulations for Hazardous Waste Management.

The regulated community may use the management and storage methods outlined in this memo or submit, for review and approval, alternative IDW management proposals on a site specific basis. The Division reserves the right to require additional IDW handling procedures as it deems necessary.

2.0 Classes of IDW

For the purposes of this policy memo IDW are separated into the following four classes:

A. Solid - includes unsaturated soil, soil saturated with water, and pre-existing solid waste;

B. Liquid - includes groundwater, drilling water and decontamination rinsate;

C. Liquid Wastes and Associated Saturated Solids, and Buried Containers

- includes liquid wastes, any solids saturated with liquid waste (i.e., a matrix containing greater than 1% liquid waste), and buried containers such as drums, electrical transformers, electrical capacitors, unexploded ordnance and any other type of container which could potentially contain a hazardous substance; and

D. Personnel Equipment

- includes equipment and supplies which are not reusable upon completion of current site activities (such as personal protective equipment and disposable sampling equipment).

3.0 IDW Management Guidelines

The Department recommends the following management guidelines (arranged by IDW class) for initial handling, segregating, storage and disposal of IDW.

3.1 Solid

These guidelines pertain to any investigatory activities which generate solid IDW, including but not limited to excavations such as boreholes, trenches and test pits.

A. All intrusive investigatory activities should be observed for evidence of buried containers or liquid waste saturated solids.

B. The preferable management alternative for all solids extracted from a site is replacement back into the same excavation from which it originated, however, consideration should be given to the likely site remedy prior to taking this action.

C. Upon excavation, all solid IDW should be placed on low permeability synthetic sheeting of thickness no less than 10 mils. No material should be stored on synthetic sheeting for a period greater than 48 hours without receiving prior Division approval. All solids stored on synthetic sheeting should be covered with similar material during all periods when excavation work is not being conducted in that area of concern.

D. When refilling excavations, the original stratigraphy of the area should be maintained to the extent feasible. If the excavation is such that it is not possible to entirely refill the excavation, as in the case of a monitoring well placement, the excess solids should be managed in accordance with Sections 3.1(C) and (E) of this policy memo unless an alternative management plan has been approved. Under no circumstances shall solid IDW from one area of concern be disposed of in a different area of concern without prior Division approval.

E. Long term storage of solids (typically periods greater than 48 hours) should be in secure containers which are suitable for potential off-site disposal (for example: roll-off dumpsters or 55 gallon drums). The contents of the containers should be characterized to determine the appropriate treatment or disposal method in a manner approved by the Division and consistent with the contaminants of concern at the site. This characterization can utilize either site investigation samples or samples whose sole purpose is to characterize the IDW.

3.2 Liquid

The following guidelines pertain to any investigatory activities which generate liquid IDW; including, but not limited to, groundwater monitoring well development and sampling, and decontamination procedures. Aquifer pump tests are beyond the scope of this policy memo and require specific Department review and approval.

A. All liquid IDW which has been extracted from a site must be stored in a secure container suitable for off-site disposal, and its contents properly characterized by Division approved laboratory analysis methods for all contaminants of concern at the site to determine the appropriate treatment or disposal method. These analysis methods should be consistent with those proposed for the site investigation work plan. This characterization can utilize either site investigation samples or samples whose sole purpose is to characterize the IDW.

B. Storage of all liquid IDW should be in a segregated manner (liquid which has been taken from the site, by area of concern, from decontamination liquid).

C. All non-decontamination liquid IDW that meets the groundwater quality standards for the

subject property's groundwater classification, as stated in the Department's Rules and Regulations for Groundwater Quality may be disposed of on-site. Liquid which exceeds these criteria shall be handled on a case by case basis. If it is anticipated that there will be exceedances of any groundwater quality standards at a site, the investigation work plan should contain a proposed management plan for this IDW.

D. The disposal criteria for all non-decontamination liquid IDW containing contaminants for which there are no RIDEM groundwater quality standards must be proposed and approved on a case by case basis. Alternative criteria for each contaminant may be proposed as concentrations of individual contaminants or groups of contaminants (i.e., total concentration of volatile organic compounds) below which there will be no demonstrated additional adverse risk to human health or the environment.

E. The preferred alternative for all liquid IDW generated as a result of decontamination procedures is disposal on site.

F. Liquid IDW which, in accordance with this memo, can be disposed of on-site should be spread uniformly over a relatively level uncontaminated portion of the site. The on-site disposal of liquid IDW may not lead to increased migration of contaminants from the site nor impact a surface water body, wetland or neighboring property to any degree, and must infiltrate the ground surface. If the volume of liquid IDW generated during a single investigation is expected to exceed 250 gallons, Division approval is required prior to any on-site disposal.

3.3 Liquid Wastes and Associated Saturated Solids, and Buried Containers

The following guidelines pertain to any investigatory activities which could potentially generate liquid wastes and associated saturated solids, or encounter buried containers, including but not limited to excavations such as boreholes, trenches and test pits.

A. Investigations in areas which are likely to encounter liquid wastes and associated saturated solids or buried containers should include a contingency plan for proper handling and disposal of these wastes in the investigation work plan.

B. The Division of Site Remediation should be contacted immediately upon the discovery of liquid wastes and associated saturated solids or buried containers for all projects which do not have a Division approved contingency plan addressing this class of IDW.

C. All liquid wastes and associated saturated solids extracted from a site should be stored in secure containers suitable for potential off-site disposal, and managed in accordance with the Department's Rules and Regulations for Hazardous Waste Management and/or the Rules and Regulations for the Investigation and Remediation of Hazardous Materials Releases as appropriate. Liquid wastes and associated saturated solids extracted from a site must be properly characterized by Division approved laboratory analysis methods for all contaminants of concern, and as necessary to determine the proper treatment or

disposal method. Under no circumstances shall liquid wastes and associated saturated solids from one area of concern be disposed of in a different area of concern without prior Division approval.

D. All buried container IDW should be extracted from its excavation upon Division approval. This approval may take the form of an approved contingency plan or an incident specific approval by Division personnel. Following extraction, buried containers should be stored in a manner which provides secondary containment for 110% of the container's volume, and managed in accordance with the Department's Rules and Regulations for Solid Waste Management Facilities, and/or the Department's Rules and Regulations for Hazardous Waste Management as appropriate. The contents of any buried containers must be properly characterized by Division approved laboratory analysis methods for all contaminants of concern, and as necessary to determine the proper treatment or disposal method. Under no circumstances should an extracted container nor its contents be disposed of on site.

E. Unexploded ordnance encountered and/or extracted from a site must be managed on a site specific basis under the direction of personnel from the State Fire Marshal's Office, the appropriate municipal Fire Department, and the Division of Site Remediation.

3.4 Personnel Equipment

All personnel equipment IDW should be ultimately disposed of off- site and must be managed in accordance with the Department's Rules and Regulations for Solid Waste Management Facilities or the Department's Rules and Regulations for Hazardous Waste Management, as appropriate. Under no circumstances should personnel equipment IDW be disposed of on site.

4.0 IDW Storage Guidelines

The investigation work plan must include provisions for the proper storage and security of IDW in the time period between the generation of the material and the determination of the appropriate treatment or disposal method. The Department recommends the following procedures for the management and storage of IDW.

A. All IDW which is determined to be a hazardous waste must be managed in accordance with the Department's Rules and Regulations for Hazardous Waste Management.

B. For investigatory activities which are likely to require storage of IDW, the site investigation work plan must include the following:

1. selected containment methods

2. the designated secure storage area

3. a schedule for IDW disposal

4. a point of contact responsible for IDW management

C. All non-hazardous waste IDW storage containers must be labelled with the following information:

1. class of IDW

2. source area

3. date of generation

4. generator name, address and phone number

D. The period of storage of non-hazardous waste IDW should logically correspond with ongoing site investigative or remedial work and be completely disposed of within 30 days of the end of that phase of site work.

ASTM and CDM Guidelines for Soil Gas Monitoring

Designation: D 5314 – 93

Standard Guide for Soil Gas Monitoring in the Vadose Zone[1]

This standard is issued under the fixed designation D 5314; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers information pertaining to a broad spectrum of practices and applications of soil atmosphere sampling, including sample recovery and handling, sample analysis, data interpretation, and data reporting. This guide can increase the awareness of soil gas monitoring practitioners concerning important aspects of the behavior of the soil-water-gas-contaminant system in which this monitoring is performed, as well as inform them of the variety of available techniques of each aspect of the practice. Appropriate applications of soil gas monitoring are identified, as are the purposes of the various applications. Emphasis is placed on soil gas contaminant determinations in certain application examples.

1.2 This guide suggests a variety of approaches useful to successfully monitor vadose zone contaminants with instructions that offer direction to those who generate and use soil gas data.

1.3 This guide does not recommend a standard practice to follow in all cases nor does it recommend definite courses of action. The success of any one soil gas monitoring methodology is strongly dependent upon the environment in which it is applied.

1.4 Concerns of practitioner liability or protection from or release from such liability, or both, are not addressed by this guide.

1.5 This guide is organized into the following sections and subsections that address specific segments of the practice of monitoring soil gas:

Section	
4	Summary of Practice
4.1	Basic principles, including partitioning theory, migration and emplacement processes, and contaminant degradation
4.7	Summary Procedure
5	Significance and Use
6	Approach and Procedure
6.1	Sampling Methodology
6.5	Sample Handling and Transport
6.6	Analysis of Soil Gas Samples
6.7	Data Interpretation
7	Reporting

1.6 *This guide does not purport to set standard levels of acceptable risk. Use of this guide for purposes of risk assessment is wholly the responsibility of the user.*

1.7 The values stated in either inch-pound or SI units are to be regarded separately as the standard. The values given in parentheses are for information only.

1.8 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Descriptions of Terms Specific to This Standard:*

3.1.1 *capillary fringe*—the basal region of the vadose zone comprising sediments that are saturated, or nearly saturated, near the water table, gradually decreasing in water content with increasing elevation above the water table. Also see Terminology D 653.

3.1.2 *contaminant*—substances not normally found in an environment at the observed concentration.

3.1.3 *emplacement*—the establishment of contaminant residence in the vadose zone in a particular phase.

3.1.4 *free product*—liquid phase contaminants released into the environment.

3.1.5 *free vapor phase*—a condition of contaminant residence in which volatilized contaminants occur in porosity that is effective to free and open gaseous flow and exchange, such porosity generally being macroporosity.

3.1.6 *liquid phase*—contaminant residing as a liquid in vadose zone pore space, often referred to as "free product."

3.1.7 *macroporosity*—large intergranular porosity with large pore throats, including soil cracks, moldic porosity, animal burrows and other significant void space.

3.1.8 *microporosity*—intragranular porosity and microscopic intergranular porosity with submicroscopic pore throats.

3.1.9 *occluded vapor phase*—condition of contaminant residence in which volatilized contaminants occur in porosity that is ineffective to free and open gaseous flow and exchange, such porosity generally being microporosity; frequently termed dead-end pore space.

3.1.10 *partitioning*—the act of movement of contaminants from one soil residence phase to another.

3.1.11 *soil gas*—vadose zone atmosphere.

3.1.12 *solute phase*—a condition of contaminant residence in which contaminants are dissolved in ground water in either the saturated or the vadose zone.

3.1.13 *sorbed phase*—a condition of contaminant residence in which contaminants are adsorbed onto the surface of soil particles or absorbed by soil organic matter.

3.1.14 *vadose zone*—the hydrogeological region extending from the soil surface to the top of the principal water table.

4. Summary of Guide

4.1 Soil gas monitoring in the vadose zone is a method used to directly measure characteristics of the soil atmosphere that are frequently utilized as an indirect indicator of processes occurring in and below a sampling horizon. Soil gas monitoring is used as a method to suggest the presence, composition, and origin of contaminants in and below the vadose zone. Among other applications, this method is also employed in the exploration for natural resources, including petroleum, natural gas and precious metals. Soil gas monitoring is a valuable screening method for detection of volatile organic contaminants, the most abundant analytical group of ground-water contaminant compounds (1).[7]

4.2 *Basic Theoretical Principles*—The processes indicated by the soil gas monitoring method are partitioning, migration, emplacement and degradation. Partitioning represents a group of processes that control contaminant movement from one physical phase to another, these phases being liquid, free vapor (that is, through-flowing air (2)), occluded vapor (that is, locally accessible air and trapped air (2)), solute and sorbed. Migration refers to contaminant movement over distance with any vertical, horizontal or temporal component. Emplacement refers to establishment of contaminant residence in any phase within any residence opportunity. Degradation is the process whereby contaminants are attenuated by oxidation or reduction in the vadose zone, either through biogenic or abiogenic processes. Soil gas monitoring measures the result of the interaction of these processes in a dynamic equilibrium. Measurement of these processes in static equilibrium is unrealistic.

4.3 The following subsections provide detailed information on partitioning, migration, emplacement and degradation. Subsection 4.4 provides a summary procedure for soil gas sampling. Users of this guide who do not wish to study details of partitioning, migration, emplacement and degradation at this time may skip to 4.4.

4.3.1 Partitioning is the initial step by which contaminants begin to move away from their source. Partitioning occurs in water saturated and unsaturated environments. This group of processes is complex and difficult to quantify when considered in the vadose zone due to the unique makeup of the vadose matrix, i.e. air-filled porosity (microporous and macroporous), pore water, free product, solid-phase soil organic matter, clay and discrete inorganic soil particles. Important individual processes of partitioning are dissolution, volatilization, air-water partitioning, soil-water partitioning and soil-air partitioning (3).

4.3.2 Dissolution is the process whereby volatile contaminants move between the liquid phase (free product) and the solute phase (dissolved in water). At equilibrium, the product of the mole fraction of a particular compound in the liquid phase and the activity coefficient of that compound in the liquid phase is equal to the product of the mole fraction of

[5] *Annual Book of ASTM Standards*, Vol 14.02.
[6] *Annual Book of ASTM Standards*, Vol 14.01.
[7] The boldface numbers given in parentheses refer to a list of references at the end of the text.

that compound in the solute phase and the activity coefficient of that compound in the solute phase. This process is more clearly described by the following expression:

$$X^L_I \Gamma^L_I = X^W_I \Gamma^W_I \quad (1)$$

where:

X^L_I = the mole fraction of compound (I) in the liquid (L) phase (free product),

X^W_I = the mole fraction of compound (I) in the solute (W) phase (dissolved in water),

Γ^L_I = the activity coefficient of compound (I) in the liquid (L) phase (free product), and

Γ^W_I = the activity coefficient of compound (I) in the solute (W) phase (dissolved in water).

Dissolution equilibrium is therefore influenced by concentration of the subject compound in both the free product contaminant mixture and water. The most common practical application of expression Eq (1) in soil gas monitoring is in hydrocarbon detection. Simplification of Eq (1) is achieved by the following:

assume:

$$\Gamma^W_I = 1/S_I,$$

where:

S = the solubility of compound (I) in water

and:

$\Gamma^L_I = 1$, acceptable for hydrocarbons (3),

then:

$$X^W_I = X^L_I S_I \quad (2)$$

4.3.2.1 Dissolution equilibrium is impacted by the presence of liquid phase cosolvents, such as gasoline additives, at low concentrations in liquid phase mixtures. This change in dissolution equilibrium can enhance the solubility of certain liquid phase components in water beyond what is indicated by partitioning coefficient data generated in the laboratory. This can have significant impact on downstream concentrations of the contaminant(s) in the soil atmosphere.

4.3.2.2 The effects of temperature upon dissolution equilibrium are generally insignificant for aliphatic hydrocarbons between 15 and 50°C (4), the temperature range from which most soil gas samples are recovered. However, temperature effects upon dissolution equilibrium can be significant for other common families of contaminant compounds within similar temperature ranges (5). These effects must be considered when planning or interpreting the results of a soil gas survey.

4.3.2.3 Dissolution equilibrium is altered by changes in water salinity. Modest decreases in the solubility of contaminants in water are to be expected with increases in salinity of the solution.

4.3.2.4 The rate of dissolution is strongly dependent upon the partitioning coefficient of the particular contaminant of interest and the amount of mixing of the liquid phase and water (3). For example, partitioning of a particular contaminant into ground water is accelerated by frequent water level fluctuations within a contaminated capillary fringe. The downstream implications for subsequent partitioning of the contaminant from the solute to the vapor phase for eventual soil gas recovery are obvious.

4.3.3 Volatilization is the process during which volatile contaminants move between the liquid phase (free product) or solute phase and a vapor phase, either the free vapor phase or the occluded vapor phase or both. Contaminant mixtures can contain compounds with a considerable range of vapor pressures that can contribute contaminants to the soil atmosphere by volatilization. This atmosphere will exhibit a composition similar to that of the parent contaminant but lacking in those constituents with the lowest vapor pressures. The likelihood of the presence of a particular contaminant introduced into the soil atmosphere by volatilization can be estimated by considering the partial pressure of that contaminant in a vapor phase. This partial pressure is equal to the product of the mole fraction concentration of the subject component in the liquid contaminant solution, the activity coefficient of the subject component and the vapor pressure of the pure component. This concept is more clearly expressed as follows:

$$P = X_I \Gamma_I P^o \quad (3)$$

where:

P = the partial pressure of the subject contaminant compound in the vapor phase,

X_I = the mole fraction concentration of contaminant (I) in the liquid contaminant solution,

Γ_I = the activity coefficient of the subject contaminant in the liquid contaminant solution, and

P^o = the vapor pressure of the pure component.

4.3.3.1 The quantity of contaminant volatilized into a vapor phase and the rate of that process is strongly dependent upon temperature. Rate of volatilization is also controlled by the rate of transport of contaminant vapors from the liquid phase-vapor phase interface (3). This rate is probably higher when macroporous flow paths are available for vapor phase transport, and is promoted by a number of driving forces. These are concentration gradient, density gradient between soil atmosphere and contaminant-saturated soil atmosphere, convection currents related to temperature gradient, barometric pressure pumping and introduction of water onto the liquid phase-vapor phase interface.

4.3.4 Air-water partitioning is the process by which volatile contaminants move between the solute phase and a vapor phase, either the free vapor phase or the occluded vapor phase or both. For dilute solutions, air-water partitioning is controlled by Henry's Law, which states that the vapor pressure of a volatile compound above a dilute aqueous solution of that compound is equal to the product of the Henry's Law constant and the mole fraction of that compound in the aqueous solution. Henry's Law may be represented as:

$$P_I = kX_{I(aq)} \quad (4)$$

where:

P_I = vapor pressure of compound (I) above a dilute aqueous solution of (I),

k = the Henry's Law constant for compound (I) at a given temperature, and

$X_{I(aq)}$ = the mole fraction of the subject contaminant compound in the aqueous solution.

Care must be exercised in using Henry's Law to approximate contaminant vapor pressures because of unknowns related to the concentration of contaminants in solution and the contribution of other partitioning processes. Some available literature pertaining to soil gas surveying places emphasis on

Henry's Law constant at 25°C and atmospheric pressure as a primary controlling factor in determining the suitability of a particular volatile contaminant to the soil gas monitoring method. Such emphasis may be inappropriate when, for example, free product is the source of contaminant vapors or when contaminants have not reached ground water. Care must also be exercised in noting the units in which Henry's Law constants are expressed, as these vary from source to source. Volatile but very highly water soluble compounds behaving according to Henry's Law may not be detectable in soil gas because of their persistence for residence in the solute phase (6).

4.3.5 Soil-water partitioning is the process by which volatile contaminants move between the sorbed phase and the solute phase. This process is generally underestimated in its importance to the success or failure of contaminant recovery by soil gas sampling, especially when utilizing the majority of active soil gas sampling techniques generally available to field personnel.[8] There is uncertainty with respect to factors controlling soil-water partitioning, creating doubt as to the reliability of soil sorption data in most applications. Problems with soil sorption data include variability in measurement protocols, the variable nature of organic matter in soils, the effect of dissolved organic matter, unusual pH effects and the effect of salinity, among others (3).

4.3.5.1 The contribution of soil-water partitioning to contaminant phase residence equilibria is strongly controlled by sorbed contaminant concentration in soil, soil makeup, vadose zone pore water content, and soil porosity configuration. Important variables in soil makeup are the quantity, type and distribution of clay in soil and the quantity, type and distribution of soil organic matter. These variables impact the surface area available to sorptive processes, that is, the storage capacity of the soil for contaminants in the sorbed phase, and the pH of the sorption environment. Variations in vadose zone pore water content directly affect the storage capacity of the soil for contaminants in the solute phase. Soil porosity configuration, principally microporosity versus macroporosity, is critical to the rate of soil-water partitioning due to the contrast in surface area between micropores and macropores and the related storage capacity of this porosity for both pore water and sorbed contaminants.

4.3.6 Soil-air partitioning is the process by which volatile contaminants move between the sorbed phase and a vapor phase, either the free vapor phase or the occluded vapor phase or both. Like soil-water partitioning, this process is underestimated in its importance to the recoverability of contaminants by many soil gas sampling techniques. In vadose zone horizons with very low pore water contents, soil-air partitioning can yield vapor phase contaminant composition that differs from free product composition. In vadose zone horizons with higher pore water content, the responsibility for this compositional inconsistency is shared, largely with soil-water partitioning. In wet soil conditions, threshold soil water content values exist for trapped soil atmosphere content to become significant (7), suggesting that responsibility for this compositional inconsistency can b largely attributed to occluded phase residence. Additiona important variables are soil clay content, type and distribu tion, and soil organic matter content, type and distribution Studies have demonstrated significant impact of soil organi matter and clay content on volatile organic compoun emissions from soils (8). Due to the strong control on vapo phase contaminant content by the soil-air partitioning pro cess, it is unreasonable to expect soil contaminants with high affinity for sorption to be efficiently recovered by most soi gas sampling techniques.

4.4 Migration of contaminants in the vadose zone, that is unsaturated flow, is highly complex and is controlled by soi characteristics, contaminant composition and contaminan phase (9). Migration through unsaturated matrix can occu through a variety of diffusion, dispersion and mass transpor mechanisms which behave in a manner unique to saturate flow.

4.4.1 A major division in migratory behavior of contami nants is defined by their solubility or immiscibility in wate Contaminants are often introduced into the soil as liqui mixtures, the components of which immediately begin t partition into other phases upon soil entry. Contaminant that establish soil residence behind a migratory front chang in composition with distance from their point of entry. A contaminant migration continues, pathways for individua components can become divergent, such that the composi tion of the liquid mixture continues to change as migratio proceeds. Eventually, migration of liquid mixtures ma reach ground water. This can be retarded if the contaminant partition into other phases before reaching ground water an if contaminant vapor is less dense than the uncontaminate soil atmosphere. Transport of contaminants by downwar percolation of meteoric waters and upward movement o ground water accelerate the contact of contaminants wit ground water. When these contaminants do reach groun water, a radically different set of migration mechanism begins to govern contaminant transport via saturated flow Further divergence of contaminant pathways is dependen upon the tendency of each component of the contaminan mixture to float on ground water, become dissolved i ground water or sink to an impermeable layer within th aquifer. Detailed descriptions of these phenomena are avail able in the literature (10).

4.4.2 The impact of migration processes on soil gas measurement is significant. Although it is impractical to estimate actual migration mechanisms by modelling prior to most soil gas monitoring efforts, a rudimentary knowledge of site characteristics can guide investigators to realistic inter pretations of soil gas data expressing unusual or highly variable compositions. More thorough knowledge of relevant site characteristics, such as the presence or absence of barriers to vertical or horizontal migration, that is, founda tions, buried pavement, or perched ground water, as well as preferential pathways for contaminant migration, that is backfill rubble, utility vaults, storm sewers or soil cracks, can assist investigators to assess the migration impact on soil gas survey design.

4.5 The vadose zone is a highly complex soil-air-water-hydrocarbon system with abundant opportunity to store contaminants in all phases. Contaminants partition ac

[8] See 6.2 for a discussion of active soil gas sampling techniques.

cording to their physical properties and the residence opportunity presented to them along their migratory path. This process has been described as an in-situ chromatographic-like separation of contaminants (11). Emplacement, or the establishment of contaminant residence, is a highly dynamic process. Contaminants move from one phase to another as changes occur in both chemical and physical equilibria. Important changes impacting phase residence change include temporal variations in moisture content, soil temperature and level of microbial activity.

4.5.1 One interesting example of disruption in equilibrium conditions is the act of sampling soil gas. Many soil gas sampling systems rely on large volume recovery of soil gas to provide a sample that is believed to be representative of the soil atmosphere in situ. Movement of this soil gas by convective flow through unsaturated soils can cause upward changes in vapor phase contaminant concentration at the expense of other phases.

4.5.2 In natural systems, temporal increases in soil moisture cause gradual increases in solute phase emplacement at the expense of other phases. It is unrealistic to attempt to characterize a static soil gas equilibrium in the vadose zone because this equilibrium is never achieved. For this reason, soil gas data sets based on specific contaminant concentrations and generated at different times are usually not comparable for the absolute values generated by each temporal sampling event. Qualitative comparison of data generated by the same soil gas method and performed at different times is permissible. Generation of a single data set by reconnaissance soil gas sampling and subsequent infilling of data to form a single data set is strongly discouraged.

4.5.3 Attempts to compensate for temporal variations in phase equilibria have been attempted by collecting samples that approximate replicates at known locations and adjusting succeeding data up or down to compensate for observed changes. This procedure is also strongly discouraged, because the number of variables affecting observed changes are too great. Moreover, the ability or willingness of most investigators to determine the most significant effects upon phase equilibria is insufficient to be of use.

4.5.4 Data sets generated by different soil gas sampling techniques may not be comparable as a direct result of differences in efficiency of recovery of contaminants from specific phases. Not only can these data sets differ in measured contaminant concentration, but they can vary substantially in composition as well.

4.6 Degradation of contaminants occurs in the vadose zone through oxidation or reduction reactions that can be biogenic or abiogenic in nature. This process can occur both aerobically and anaerobically to mitigate contaminant levels. Degradation is most often recognized in shallow, permeable soils where favorable conditions exist for oxidation of labile compounds, however other vadose environments can be conducive to degradation. Specific environmental conditions are required for degradation processes to occur. For abiogenic degradation, redox potential and soil pH can be rate controlling factors. For biodegradation, necessary environmental conditions include the presence of microorganisms capable of adaptation to the contaminant as substrate, conditions favorable to population increases of these microorganisms and migration pathways for contaminants to come in contact with these microorganisms. Most soils contain naturally occurring populations of various microorganisms that can degrade petroleum products (12). Contaminant biodegradation is known to occur in groundwater (13) and in soils (14) prior to contaminant partitioning into a vapor phase. Contaminant biodegradation rates for some compounds are highly variable and are controlled by a number of kinetic factors influencing the distribution of microorganisms responsible for degradation. These include aerobic versus anaerobic environments, contaminant type and temperature (15, 16).

4.6.1 Degradation rate can approach, equal or periodically exceed the rate of contaminant emplacement into the vadose zone, such that contaminants are not detectable by soil gas monitoring. This mechanism can result in soil gas data which are not representative of an underlying contaminated condition (17).

4.6.2 Labile contaminants can be degraded to compounds that may or may not be detectable in soil gas. Aerobic degradation can produce carbon dioxide which can be monitored as an indirect indicator of the presence of contaminants (18), or organic acids and phenols (13) that are not routinely detectable in active whole air soil gas samples. In alternative to whole air methods, use of an appropriate adsorption medium may facilitate recovery of such compounds for analysis by desorption and gas chromatography-mass spectroscopy. Anaerobic degradation can produce compounds including methane, ethylene, propylene, acetylene, and vinyl chloride which also can be monitored as an indirect indicator of the presence of contaminants. Caution must be used in attributing elevated levels of these compounds to biodegradation, because competitive processes can confuse the interpretation of absolute concentration values and potential sources.

4.6.3 Biodegradation of contaminants in the vadose zone can proceed naturally by adaptation of indigenous microbial populations to metabolize contaminants as primary substrate, or by introduction of foreign populations which have been preconditioned to metabolize contaminants of interest. Case histories demonstrate the absence of certain compounds in soil gas contaminant suites for which biodegradation has been named as the responsible process (17, 19, 20). Such cases address the attenuation or complete absence of simple aromatic hydrocarbons, some of which are halogenated, in soil gas. This phenomenon may be controlled by the availability of oxygen as has been demonstrated in the laboratory (13). Other compound classes can exhibit similar effects.

4.6.4 Other processes may share responsibility for the actual or apparent absence or attenuation of some contaminants in soil gas sample sets. In some cases where attenuation of contaminant concentration is attributed to degradation, combinations of high soil clay, organic matter and pore water content can reduce the recovery efficiency of certain soil gas sampling techniques for certain contaminants such that contaminant concentrations fall below detection limits. Care must be exercised in attributing a lack of contaminants in soil gas samples to degradation.

4.7 *Summary Procedure for Soil Gas Sampling*—Vadose zone monitoring methods have a set of procedures, both general and specific, that must be consistently followed in

order to provide maximum data quality and usefulness. Soil gas monitoring is no exception, with six primary procedures common to all soil gas monitoring techniques. The procedures are a planning and preparation step including definition of data quality objectives, the act of sampling soil gas in the field, handling and transporting the sample, sample analysis, interpretation of the results of analysis, and preparation of a report of findings.

4.7.1 The planning and preparation step begins with the formulation of project objectives, including purpose of the survey, appropriate application of the data to be collected and data quality objectives.

4.7.2 Data can vary in quality due to sampling methodology, sample preparation, analytical procedures, laboratory quality control, and available documentation. Quality assurance programs include all of the activities necessary to provide measurement data at a requisite precision and bias (see Practice 1357). Quality assurance objectives for soil gas monitoring are similar to those for atmospheric air monitoring. The overall quality assurance objective for measurement data is to ensure that data of known and acceptable quality are provided. In order to meet these objectives, data quality objectives should be defined for data measurements in support of the soil gas data interpretation. These are comparability, completeness, representativeness, bias and precision. The comparability of the data collected refers to the ability to interpret the results in light of previous data collection efforts. Completeness refers to the number of samples collected and analyzed compared to the planned number of samples. Representativeness is a measure of the degree to which analytical results reflect true field conditions. Field contamination and sampling intensity are two factors affecting representativeness. Bias is a generic concept of exactness related to the closeness of agreement between the average of one or more test results and an accepted reference value (see Practice E 177). The precision of a measurement process is a generic concept related to the closeness of agreement between test results obtained under prescribed like conditions from the measurement process being evaluated. Overall precision and bias targets for chemical contaminant measurements can be set at 10 % allowable deviation with 90 % confidence limits. In all of these quality assurance activities one must take into consideration that factors including geophysical conditions and definition of sampling volume in the vadose zone often have higher variability than analytical equipment calibration procedures.

4.7.3 Table 1 provides suggested quantitative limits for data quality objectives.

4.7.4 The planning and preparation step continues with the evaluation of available information already gathered for the project area. These efforts culminate in the selection of an appropriate soil gas monitoring method and a survey design which best fits the project objectives within budgetary constraints. Prior to actual field work, investigators must obtain the necessary permits and landowner permission for property access. When a survey area is pending sale, investigators should obtain written permission to conduct the survey from both the buyer and the seller. Moreover, when a soil gas survey is being performed as a service, no work should proceed on the survey without a fully executed consulting agreement between the investigator and the client for whom the survey is being conducted.

TABLE 1 Suggested Quantitative Limits for Data Quality Objectives

QA/QC Objective	Measure	Formula	Limit
Accuracy	Laboratory standard	Standard recovery	90 to 110 %
Precision	Field replicate	Relative standard deviation	< 20 %
	Laboratory replicate	Relative standard deviation	< 20 %
Representativeness	Air blank	Bias	< 10 %
	Cross contam. blank	Bias	< 10 %
Completeness	Completion (%)	Relative compl.	> 90 %
Comparability	Prof. judgment	NA	NA

4.7.5 Actual field work consists of recovery of soil gas samples. The method selected should be based upon site specific factors and dictated by the project objectives. A detailed discussion of soil gas sampling methods is provided in 6.1.

4.7.6 As samples are being recovered, they must be handled and transported in such a way as to assure preservation prior to analysis. A detailed discussion of sampling and transport is located in 6.5.

4.7.7 The presence of contaminants is determined through analysis of the soil gas samples. This step is controlled to a large degree by the QA/QC objectives of the survey. A discussion of sample analysis is provided as 6.6.

4.7.8 Data interpretation is largely an iterative process of review of the raw soil gas data out of context, a review of the soil gas data in context of other site characteristics and the formulation of conclusions based upon all known information. A discussion of soil gas data interpretation is located in 6.7.

4.7.9 Finally, a report of findings is generated in a format that is selected to be appropriate to the requirements of the end users. Section 7 provides options that can be addressed in reporting as well as recommendations of topics that should be included in all soil gas summations.

5. Significance and Use

5.1 *Application of Soil Gas Monitoring*—Soil gas monitoring is an extremely versatile method in that it can be adapted to conform to the requirements of dissimilar industries for a wide variety of applications. A number of soil gas techniques have been utilized in the agricultural (21), petroleum (22, 23) and minerals (24) industries. Certain applications have been exercised for well over 50 years. Soil gas monitoring has been utilized in research efforts, including the monitoring of underground coal gasification retorts (25). Application to the environmental industry is comparably recent but very effective as a rapid and relatively inexpensive method of detecting volatile contaminants in the vadose zone. Field screening, of which soil gas monitoring is a basic component, has been demonstrated to be effective for selection of suitable and representative samples for other more costly and definitive monitoring methods (26). Soil gas monitoring is useful to assess the extent of ground water contamination for certain contaminants and field environments (27). Soil gas monitoring is also a viable method of monitoring subsurface contaminant discharges from underground storage tanks (28). New applications of the soil gas

monitoring are periodically developed and published in the referenced literature. The method may be useful in the study of unsaturated flow. In most instances, the method can make use of very light-weight, portable and inexpensive tools made from commonly available materials. Soil gas monitoring has become a widely accepted method for locating subsequent environmental monitoring and remediation activities such as ground water monitoring wells, contaminant product recovery wells or excavations to recover contaminated soil. Soil gas monitoring has made a significant contribution to ground water monitoring and remedial planning on sites that fall under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) (29). This method is highly useful at the initiation of Phase II environmental assessment action in determining the presence of volatile organic contamination of real property in a pending sale.

5.1.1 In any application, soil gas monitoring can be performed over a wide range of both spatial and temporal designs. Spatial designs include soil gas sampling in profiles or grid patterns at a single depth or multiple depths. Multiple depth sampling is particularly useful for contaminant determinations in cases with complex soil type distribution and multiple sources. Depth profiling can also be useful in the determination of the most appropriate depth(s) at which to monitor soil gas, as well as the demonstration of migration and degradation processes in the vadose zone. Temporal designs include the long-term monitoring of the vadose zone for the appearance of volatile organic contaminants from known potential sources such as underground storage tanks and solid waste landfills. Temporal designs are especially useful in monitoring the effectiveness of contaminant remediation efforts.

5.1.2 Soil gas monitoring in the vadose zone is an ideal reconnaissance tool and screening technique in most applications. However, site specific and contaminant specific limitations can cause this technique to be unsuccessful in meeting project objectives. Caveats exist in all soil gas monitoring procedures that can frustrate efforts to successfully apply the method to any application.

5.2 *Limitations*—The most significant limitation on soil gas monitoring is the inability to utilize the method as a stand alone technique. Soil gas monitoring does not provide repeatable quantitative information over time due primarily to the dynamic nature of phase equilibria in the vadose zone and secondarily to unavoidable inconsistencies in sampling practice. As a result of geologic variability in the vadose zone and the multitude of unique sampling devices currently being used in the field, quality assurance and quality control protocol, discussed in 6.4, cannot provide the rigor required as in a test method. For these reasons, soil gas data in itself cannot be used to provide definitive answers about the location or absence of buried contaminants. Moreover, the success of any soil gas monitoring method is strongly dependent upon effects related to geologic variation and moisture content in the sampling horizon as well as the physical properties of the target contaminants.

5.2.1 False negative results can occur as a direct result of the incompatibility of a specific procedure with the properties of the sampling horizon or the target contaminants, or both. Soil gas data cannot be used to establish bulk volume or the commerciality of buried petroleum, natural gas, or ore bodies.

5.2.2 With the necessary analytical procedures, soil gas can be examined for compositional anomalies, a very useful technique for multiple source problems. In some instances, contaminant occurrences are limited to single species (compounds, mercury, etc.), however more often than not the contaminant source is a mixture of organic chemicals that have a unique chemical compositional character consisting of both normally evaluated priority pollutants and non-priority pollutant chemicals that may be overlooked. By identifying and using compositional information, many problematic site situations such as degradation can be minimized by targeting the more refractory compounds associated with the contaminant occurrence. This interpretive method is impossible to model for an industry wide application due to variation in methods and technique.

5.2.3 A basic limitation of the technique is that due to the ease of procurement and use of soil gas sampling devices, there is a tendency for inexperienced personnel to oversimplify any and all aspects of the method. Investigators must consider the experience level and technical ability of personnel who acquire soil gas samples and attempt to interpret the results. Certain procedural facets are not trivial, as discussed in Section 6. The results of certain techniques tend to be affected by minor variations in procedure despite apparent adherence to a "Standard Operating Procedure."

5.2.4 Atmospheric air contamination is not a trivial problem corrected by simple device-oriented field practice. Many sampling systems recover very large volumes of "soil gas" that may actually represent a mixture of soil gas and atmospheric air. This mixing occurs through the introduction of ambient air adjacent to the sampling device and through macroporous pathways in the soil which are far from the sampling device. Some environmental investigators avoid the impact of this problem by reasoning that contaminant quantities in the soil are so great that they are detected despite atmospheric mixing. For qualitative approaches with non-rigorous quality assurance/quality control (QA/QC) objectives this mixing problem can be insignificant. For detection of compounds that exhibit only marginal partitioning preference for the free vapor phase, the mixing problem can be a fatal flaw in procedure. Moreover, contaminant concentration and composition investigations can be rendered useless by variations in the magnitude of mixing at various sample locations and depths in a survey area.

5.3 *Comments on Limitations of Soil Gas Monitoring*—Many investigators believe that soil gas monitoring is not an effective vadose zone monitoring method for certain volatile organic applications, in certain geographic regions or during certain seasons of the year, or both. The applicability of soil gas monitoring is controlled by physical and chemical properties and processes in the subsurface and not by factors that are obvious at or above the surface. For example, one common misconception is that soil gas monitoring is not effective during the winter season. The impacts upon soil gas measurement of elevated soil pore water content, reduced vadose zone temperature and the presence of frost, typical of numerous regions in winter, are obvious for many facets of most soil gas monitoring methods. Modification of standard operating procedure, such as an increase in sampling depth,

or selection of another soil gas monitoring method altogether can minimize the negative impacts of seasonal field conditions. It is important to understand that the responsibility for success or failure in soil gas monitoring can reside as much in the planning phase of a survey, including the method chosen, as in factors controlling the chemical and physical processes at work in the subsurface. Even with apparently ideal field conditions and with a carefully planned survey, soil gas monitoring can succeed or fail due to unknown factors controlling contaminant migration and emplacement. Soil gas monitoring is no different than any other measurement method, in that investigators must maximize effort in planning and implementation of procedure to maximize the likelihood of success.

6. Approach

6.1 *Sampling Methodology*—Soil gas sampling methodology has evolved over time and through practice in several industries. The equipment with which to perform this monitoring technique is highly varied, although it may be categorized into basic types (see 6.2.2). The literature provides numerous discussions about the design of some of this equipment (**10, 30, 31, 32, 33**). The selection of a soil gas sampling method involves consideration of three primary issues. These are the type of sampling system, the methodology of application of that sampling system and the rigor of the field QA/QC protocol. Each of these issues is discussed in this guide, however, no single method or procedure is recommended to the reader due to the variation in site specific factors. As many as one hundred unique soil gas sampling systems exist that arise from variations or combinations, or both, of the many facets described in this guide. Some systems are highly versatile for numerous applications. Others are functional for more limited or specific applications. Informed investigators must assume the responsibility of selecting the technique most appropriate to the subject application, whether that technique is commercially available from contractors or equipment suppliers, or reliant upon the ingenuity of the investigator in the field utilizing commonly available materials. Success in choosing an appropriate sampling device or an entire sampling system is dependent upon the investigator's level of understanding of vadose zone processes, contaminant properties and appropriate applicability of the soil gas method.

6.1.1 The application of any of these methods must be controlled by strict adherence to a standard operating procedure. Occasional deviations as dictated by unusual field conditions should be recorded in the project field notebook. Inadvertent minor deviations in field procedure can result in misinterpretation of the data acquired.

6.2 *Sampling Systems*—Six basic sampling systems exist. These are based upon the collection of soil gas by a whole-air or sorbent method in an active or passive approach, or upon the principle of collection of a soil or water sample for subsequent sampling of a contained headspace atmosphere. Contained atmosphere methods do not yield samples representative of in situ vadose zone atmospheres.

6.2.1 Whole-air methods sample the soil atmosphere as a mixture of gases, including contaminant and non-contaminant vapors. Sorbent methods sample contaminants adsorbed onto a collection medium exposed to a whole-air sample stream. Active methods are those that obtain a soil gas sample by positioning a sampling device in the subsurface and the withdrawal of soil atmosphere through the device from the sampling horizon. Passive methods are those that obtain a soil gas sample by placing a collection device in the soil or on the soil surface, and allowing the atmosphere within the device to come into compositional equilibrium with the soil atmosphere. Four of the six basic sampling systems arise from these approaches, namely the whole air-active approach, the sorbed contaminants-active approach, the whole air-passive approach, and the sorbed contaminants-passive approach. Two additional systems exist that are based respectively upon the collection of a soil or water sample for subsequent sampling of a small volume headspace atmosphere.

6.2.2 *Whole Air-Active Approach*—This method of soil gas sample collection involves the forced movement of bulk soil atmosphere from the sampling horizon to a collection or contaminant device through a probe or other similar apparatus (**10, 34**). Contained samples of soil atmosphere are then transported to a laboratory for analysis, or the sampling device is directly coupled to an analytical system. Whole air-active sampling is best suited to soil gas monitoring efforts where contaminant concentrations are expected to be high and the vadose zone is highly permeable to vapor. Probes exist that must utilize pre-existing holes or that can penetrate the vadose zone by driven means. These devices can be very simple and light-weight for low cost mobilization (**35**), or they can be affixed to vehicle mounted drills or hammers useful for larger, more complex surveys at a higher cost of mobilization. The whole air-active technique can be combined with other monitoring methods such as soil monitoring for engineering purposes (**36**) in some survey environments. The success of this practice can be highly site-specific.

6.2.2.1 Ground probes can be of small to large internal volume. The development of sampling devices with smaller internal volumes equating to smaller purge volumes is a significant improvement, providing samples which are more representative of soil atmosphere, and a greater ease of equipment decontamination between usages. Sample size can vary from a few millilitres to many tens of litres depending upon the sample rate through the probe, the vapor storage capacity of the soil and the ability of the soil to deliver vapor to a probe under vacuum.

6.2.2.2 The success of the active approach is strongly dependent upon soil clay, organic matter and moisture content. Driven probes tend to destroy natural soil permeability around the body of the probe due to soil compaction concurrent with insertion. This can be a severe limitation in moist, heavy clay soils. In very dry, cemented soils, driven probes can create radial fractures that can enhance soil permeability to vapor concurrent with insertion. These fractures can communicate atmospheric air with soil atmosphere, a limiting factor for obtaining representative, large-volume soil gas samples. The effect can be so severe as to lower recovered contaminant concentrations in the soil gas sample below the limits of analytical detection. This is especially true for highly sorptive or water soluble compounds, or both. Some investigators have attributed the poor

recoveries of these compounds exclusively to other processes, that is, degradation (21, 37).

6.2.2.3 Methods requiring a pre-existing hole for probe insertion (38) made with a commercially available "slam bar" can provide supportable contaminant data where contaminant concentrations and soil permeability to vapor are high, however the act of making a hole with a "slam bar" and subsequent removal of the "slam bar" can encourage soil contaminant venting and lower sample representativeness. Insertion of the sampling probe into this hole further degrades representativeness by additional venting of contaminants as the probe displaces the atmosphere in the hole upon insertion. Purging of the probe prior to sampling under conditions of low soil permeability and low contaminant concentration may lower contaminant levels below the limits of analytical detection. Methods requiring a pre-existing hole for probe insertion are not recommended for soil gas sampling from soils with high clay and moisture contents.

6.2.2.4 Excellent discussions of numerous whole air-active sampling systems may be found in the literature (10, 21, 37, 39). Investigators must consider the caveats and limitations of the whole air-active approach when selecting a certain method for a specific application.

6.2.3 *Sorbed Contaminants-Active Approach*—The sorbed contaminants-active method of soil gas sample collection also involves the forced movement of bulk soil atmosphere from the sampling horizon through a probe or other similar apparatus, but to a collection device designed to extract and trap sample stream contaminants by adsorption (40, 41). This system is well suited to sites where the soil may be highly permeable to vapor and where the contaminant concentration may be lower than required for successful whole-air surveys. Sorbent devices are designed to concentrate the components of interest and remove some of the soil gas components known to interfere with sample analysis.

6.2.3.1 Contaminant trapping is accomplished by use of an adsorbent collection medium such as charcoal or a carbonized molecular sieve adsorbent (43, 44), as well as porous polymers, silica gel and activated alumina (10). This approach is especially amenable to the detection of nonpolar volatile organic compounds. Organic compounds that are reactive, oxygenated or are gaseous at room temperature are either not adsorbed by or are not efficiently desorbed (42) from charcoal. Sorbent collection devices are commercially available or can be specially prepared with an appropriate sorbent material that concentrates desired compounds for future analysis. Colorimetric detector tubes are available which will provide an indication of the presence of target compounds at the time of sampling. These devices are limited in application by the high concentration requirements for many compounds and the compound-specific nature of these tubes.

6.2.3.2 The effectiveness of the sorbed contaminants-active approach can be limited by high vadose zone clay and water content, reducing the ability of the soil to transmit vapor through the sorbent trap. Commercially available sorbent traps come with information suggesting maximum, minimum and optimum sampling rate through the trap. Soil characteristics can limit flow rate to a point below the minimum recommended rate, affecting the performance of the trap and the reproducibility of adjacent samples. Interaction of the sorption media with target compounds during desorption in the laboratory can form artifacts, restricting the interpretive value of the data. Some sorption media are prone to irreversible adsorption (see Definitions D 2652). Some may be affected by high soil gas relative humidity. Humidity greater than 60 % (very common for soil gas) can reduce the adsorptive capacity of activated charcoal to 50 % for some chemicals. Presence of condensed water in the sample tube will indicate a suspect sample (see Practice D 3686). Anticipation of these problems is recommended for all sorbent techniques, and a thorough quality control plan should be designed and implemented as is discussed in 6.4 of this guide.

6.2.3.3 Special sample preparation is required for samples adsorbed onto a trapping medium. This preparation step consists of the thermal or solvent desorption of the contaminants from the trapping medium. Proper practice will promote needed accuracy and precision in the determination of contaminant concentrations above specified values (see Practice D 3687).

6.2.4 *Whole Air-Passive Approach*—This method of soil gas sample collection involves the entry of bulk soil atmosphere or soil atmosphere components from a near-surface sampling horizon to a collection or containment device through a flux chamber or other similar apparatus (30). Enclosure devices sample vaporous emissions from a known soil surface area capped by a chamber. The volume of the chamber is continuously swept by injection of a gas of known composition, and the resultant carrier gas-contaminant mixture is collected for analysis. The rate of emission or "flux" of contaminants can be calculated if flow rate of injected gas and contaminant concentration in the sample are determined.

6.2.4.1 The whole air-passive approach is useful to some very specific applications. This method may be used, for example, to monitor contaminant emissions from soil or water to assess the health hazard risk of such emissions to the general public. Determination of the extent of contamination by volatile organic compounds has been performed with whole air-passive devices, however the application of other types of systems is far more common.

6.2.4.2 A key to successful operation of a whole air-passive system is that the system is able to recover volatile compounds as they are emitted from the vadose zone. The effects of changes in barometric pressure, soil temperature and soil moisture content are not quantifiable from site to site due to site specific variables controlling vapor phase contaminant migration and the rate of contaminant partitioning into the vapor phase. The presence of contaminants or naturally occurring organic matter floating on surface water may impact the rate of entry of certain vapor phase contaminants into the chamber.

6.2.4.3 The whole air-passive method is limited in application primarily due to the great degree of dilution of contaminants in the sample stream by injected gas. This can decrease method sensitivity by lowering contaminant concentrations to levels below the detection limits of the analysis method chosen. Further decrease in method sensitivity results from the fact that soil gas contaminant concentrations are generally lower at the surface than even at nominal depths. Soil characteristics such as high water saturation, soil

cements, clay content and organic matter content will negatively impact results of these systems by restricting the rate of contaminant flux to the chamber.

6.2.4.4 Additional limitations exist. Certain devices limit flux rates into the chamber due to aspects of design. Soil macroporosity such as desiccation cracks extending beyond the collecting device will vent soil vapors to the atmosphere that will not be collected by flux chambers unless monitoring locations are biased to include these features.

6.2.5 *Sorbed Contaminants-Passive Approach*—This method of soil gas sample collection involves the passive movement of contaminants in soil to a sorbent collection device over time. Passive samplers that have been applied to sampling soil gases of environmental concern include occupational health volatile organic compound monitors (**44**) and a sampler originally developed for detecting the presence of hydrocarbons in petroleum exploration (**33, 46**). Both devices use charcoal as a sorbent; the former as a flat film and the latter coated on a wire. Passive samplers are housed in containers up to several inches in diameter, depending upon the design. They are placed open end down in holes that are usually less than 5 ft (1.5 m) deep, that are then backfilled (**32**). These monitors are generally left in place from two to ten days, although certain passive collectors can be left in place for a period of 30 days or more for certain applications. For at least one device, exposure efficiency can be determined.

6.2.5.1 The sorbed contaminants-passive approach can be employed in a wide range of geological conditions. Frozen ground and high water saturation may not limit the ability of the monitors to collect contaminants (**46**), although the composition of the contaminant suite may be impacted by related alterations in partitioning equilibria.

6.2.5.2 The sorbed contaminants-passive approach depends upon the ability of contaminants to move through the vadose zone to the passive collection device. Numerous adsorption media can be used to collect contaminants (see 6.2.4). The principle of passive-sorbent monitors relies on adsorbent reduction of the equilibrium concentration of contaminants around the monitor over time, therefore creating a concentration sink, that is, a continuous state of disequilibrium, in the vicinity of the monitor. This can encourage continued migration of contaminants toward the monitor when conditions for contaminant partitioning into the vapor phase are favorable. Migration of contaminants in the vadose zone toward a passive-sorbent device is strongly controlled by vadose zone character and the chemical and physical properties of the subject contaminants. Contaminants may move from a few feet to thousands of feet, or not at all.

6.2.5.3 Many investigators attribute the principle mechanism of contaminant migration to a passive-sorbent device to diffusion, that is, the movement of organic vapor or gas molecules from a region of high concentration to a region of low concentration as described by Fick's law (see Practice D 4597). Fick's law of diffusion states that for a constant concentration gradient, the mass of material transferred to the sampling layer can be expressed as:

$$M = \{DA(C - C_o)t\}/L \quad (5)$$

where:

M = mass of the material, ng,
D = diffusion coefficient, cm^2/min,
A = cross sectional area of diffusion cavitie(s), cm^2,
L = length of diffusion path, cm,
C = concentration at face of sampler, ng/cm^3,
C_o = concentration at adsorbing layer surface, ng/cm^3, and
t = exposure time, min.

6.2.5.4 The cross sectional area of a diffusion cavity, the length of the diffusion path and the quantity $(C - C_o)$ are impossible to accurately measure for soil gas contaminants interacting with a passive-sorbent sampler. There is some debate as to whether passive samplers measure flux or total contaminant concentration (**32**) in the vicinity of the trap. Due to the fact that the mass of the material transferred to the sampler by diffusion, a key measurement, cannot be determined, the debate will no doubt continue. It is reasonable to assume that a combination of processes is responsible for contaminant migration to sorbent traps, including diffusion, dispersion and mass transfer. All migration processes are impacted by partitioning equilibria.

6.2.5.5 Ambient air represents an atmospheric contaminant concentration sink that encourages a strong vertical vector of contaminant migration. This prevailing upward movement of contaminants from sources at depth results in contaminant concentration gradients throughout the vadose zone. The sorbed contaminants-passive method makes use of this contaminant flux (see 6.2.4) to collect long-term, nondisruptive samples of volatile contaminants. The method can collect contaminants which are compositionally representative of the contaminant mixture favoring the vapor phase. The quantity of volatile organic compounds trapped by these devices is proportional to the concentration gradients of contaminants present near the collection device and the affinity of the contaminant(s) for the collection medium.

6.2.5.6 As with active sampling protocols, specific issues exist affecting the function and calibration of passive monitors. Soil gas, even in the drier climates, will be at a relatively high humidity condition. This humidity can affect the collection efficiency of the adsorbent media. In soils of low permeability, contaminants commonly move very slowly. This can create a condition of near-zero contaminant concentration in the soils immediately adjacent to the monitor if the sorptive potential of the monitor is higher than that of the soil. When soil contaminant concentrations are rapidly depleted, that is, as the result of invasion of the sampling horizon by meteoric water, the passive monitor can source contaminants back to the soil.

6.2.5.7 The sorbed contaminant-passive approach to soil gas monitoring is not immune to the migration, emplacement and degradation factors affecting all soil gas monitoring techniques. It is not possible to measure the efficiency of passive-sorbent monitoring devices because the bulk volume of soil gas affected by the sorbent trap cannot be measured. Care must be taken not to contaminate the sorbent samples during installation or by backfilling with contaminated soil. Such care is comparable to potential problems for any measurement method in which a contaminated layer is penetrated.

6.2.6 *Soil Sampling for Subsequent Headspace Atmosphere or Extraction Sampling*—This method examines contaminants that are present in a headspace atmosphere

above a contained soil sample. Note well that this headspace atmosphere is not true soil gas (see 3.1.11), but is an artificial atmosphere formed above a potential contaminant source, that is, the soil sample. Contained atmosphere methods do not yield samples representative of in situ vadose zone atmospheres. Headspace atmospheres differ from in situ vadose zone atmospheres in that large percentages of vapor phase and moderate percentages of solute and sorbed phase contaminants can be lost in the act of soil sampling. This method is not generally recommended for a broad spectrum of cases due to numerous limitations and caveats. In comparison to other methods described in this guide, soil sampling for subsequent headspace atmosphere or extraction sampling can be a relatively poor method for determining many of the more volatile contaminants. Headspace atmospheres contain residual sorbed and solute phase contaminants that have partitioned to the vapor phase in the contained environment; most headspace approaches are reasonably efficient in recovery of some fraction of sorbed and solute phase contaminants. Contaminants in these phases in situ are recovered from a headspace after they have partitioned into the vapor phase. Recovery efficiency of contaminants in the vapor phase in situ ranges from moderate to poor.

6.2.6.1 Important criteria exist to consider when selecting a device that will provide suitable samples (see Guide D 4700). The equipment required is simple and readily available. Some commonly used augers are not suitable for soil sampling in support of subsequent headspace atmosphere sampling due to soil disturbance. Depths of auger investigations are limited by ground water conditions, soil characteristics and the equipment used (see Practice D 1452). Suitable procedures for some methods are described in the literature (47, 48). Current soil preservation practice may not apply (see Practice D 4220).

6.2.6.2 Limitations and special procedures exist for the application of soil sampling for subsequent headspace gas analysis. Filling head space with solvent can support a subsequent solvent extraction procedure. Some investigators minimize the effects of devolatilization by rapidly recovering small soil core plugs with polypropylene syringes which have been modified to accommodate recovery of soil plugs. Investigators also attempt to maximize partitioning of contaminants into the vapor phase by adding buffering solutions or sodium sulphate and phosphoric acid to the vial prior to sealing, in order to shift the activity coefficients of the subject contaminants to favor the vapor phase. Aqueous suspensions of solvent slurries of soil can be ineffective for the determination of high molecular weight labile compounds. Their persistence in soil is the result of physical entrapment in soil microporosity (49). Recovery efficiency of contaminants in soil headspace can be greatly enhanced by pulverization of the soil (50) in a ball mill or other similar apparatus. The method is biased toward recovery of contaminants in the sorbed, solute and occluded phases in situ due to the loss of pore space gas in preference to contaminants adsorbed onto the soil particles or trapped in soil micropores. Contaminant degradation, especially biodegradation, in the container is encouraged by the creation of an aerobic, moist environment during sample handling and transport prior to analysis. However, a simple method to minimize the effects of biodegradation can be achieved by storing samples, when necessary, at approximately 4°C in the dark.

6.2.6.3 Acid extraction of volatile organic compounds is widely used in geochemical exploration for petroleum and natural gas. Soil samples are placed in a closed vessel, heated and evacuated to remove vapor phase contaminants. The addition of acid to the evacuated chamber causes release of hydrocarbons believed to be bound to the soils by carbonates (22). Hydrocarbons are determined by analysis of resulting vessel atmospheres. Refinements to this method have been developed (48), however the method is designed not to determine compounds in the vapor, sorbed, or solute phases. Method sensitivity is therefore greatly reduced.

6.2.7 *Soil Pore Liquid Headspace Gas Approach*—In the vadose zone, soil gas monitoring can be accomplished in combination with soil pore liquid sampling through the use of a suction lysimeter, a pan lysimeter or a free drainage glass block sampler. The suction lysimeter installed in the vadose zone is most commonly employed for this purpose. Temporally designed surveys are ideally suited to this method.

6.2.7.1 After a lysimeter has been installed for some period of time, initial aliquots of vapor sampled from a soil pore liquid sampler will be in compositional equilibrium with solute phase contaminants when pore liquid tensions are within the operating range of the lysimeter and if pore sizes are not so great as to cause loss of hydraulic contact between the soil and the porous segment of the lysimeter. Subsequent aliquots of soil gas may compositionally resemble soil vapor in situ if soil atmosphere enters the porous segment of the sampling device. When the lysimeter cannot recover a pore liquid sample, the soil gas recovered will be compositionally similar to soil vapor in situ.

6.2.7.2 The most common effort to recover soil gas from a suction lysimeter occurs when polytetrafluoroethylene (PTFE) porous segments are employed in sampling environments with high soil moisture tensions (low moisture contents). At tensions above 60 to 80 centibars, soil pore liquid samples cannot be collected (see Guide D 4696). However, soil gas can be recovered through the porous segment and collected at the surface. This alternative sampling effort can monitor soil vapor contaminants utilizing an otherwise unsuccessful procedure until soil moisture contents increase or until an alternative soil pore liquid sampler can be installed.

6.2.7.3 This technique is limited by the relative expense and complexity of installation of the sampling devices as a primary soil gas sampling method. The completeness criterion for quality assurance is difficult to satisfy due to the inability to anticipate the performance of the soil pore liquid sampler with respect to vapor recovery. Moreover, compositional bias toward solute phase contaminants and contaminants volatilized from free product is likely in soil gas samples recovered concurrently with soil pore liquid samples.

6.3 *Methodology in Application of a Sampling Technique*—The likelihood of success of the soil gas sampling technique selected is controlled in part by the methodology in application of that sampling technique. This methodology should be guided by the objectives of the subject project and the perceived spatial and temporal array of the potential sampling targets.

6.3.1 *Grids*—Many problems suitable for soil gas monitoring are best solved by obtaining data distributed over a geographic area. Sampling in grid patterns of variable design and spacing can be a very effective way to provide data coverage over a large area for a very low cost of acquisition. Common applications of soil gas grid sampling are environmental contaminant assessments, exploration for natural resources and the siting of locations for other monitoring or exploratory techniques. Compositional analyses in conjunction with properly designed grid systems are often fundamental to successful evaluation of soil gas monitoring.

6.3.1.1 Grid spacing provides for the location of soil gas samples in grid cells. The selection of grid cell size is strongly dependent upon the relationship between project confidence level requirements and cost budget. Small survey targets and complex vadose zone geology require decreased spacing between soil gas sample locations for grid methodology to be successful. Some applications, for example, defining the boundaries of contaminated soil or ground-water contaminant plumes, may require the grid cell area to be as small as 100 to 400 ft^2 (9 to 37 m^2). Most applications to natural resource exploration monitor naturally occurring volatile compounds in soil atmospheres, requiring closely spaced grids to increase the signal to noise ratio. However, a closely spaced exploratory grid equates to a broadly spaced grid for environmental application in most situations. Common petroleum exploration grid spacing utilizes a grid cell area of approximately 250 000 ft^2 (23 000 m^2), however grid cells can range from 10 000 to 1 000 000 ft^2 (9 to 90 000 m^2) depending upon perceived reservoir target area. Widely spaced grid sample arrays are useful in reconnaissance applications such as the establishment of contaminant baselines or evaluation of the exploration potential of a geologic basin. Grid cells for such purposes can be as large as a square mile or more.

6.3.1.2 The tendency exists for investigators with constrained budgets to utilize overly large grid cell spacings. This action normally results in inadequate, over-interpreted data supporting meaningless conclusions. Care must be taken to avoid this caveat.

6.3.1.3 Grid arrays can be designed as regularly spaced and predetermined locations for soil gas sampling or they can be irregularly spaced and continually field modified. Predetermined and widely spaced grid patterns are most useful for reconnaissance work, while closely spaced, irregularly situated or field modified soil gas grid sample sites, or both, are commonly used when targeting contaminant plume boundaries, contamination from underground storage tanks or other detail work.

6.3.1.4 Multiple depth sampling, discussed in 6.3.3, when coupled with a soil gas grid sampling methodology, can provide useful data in complex geologic settings and sites with multiple contaminant sources. Computer mapping of closely spaced three-dimensional soil gas grids can provide the investigator with horizontal or vertical cross sections through the subject site, making difficult observations possible.

6.3.2 *Profiling*—Profiling is a soil gas sampling methodology useful to test a linear array for the existence of contaminants. Profiling is most often performed by sampling at closely spaced intervals in a linear array and is displayed as contaminant concentration or composition versus distance sampled on an $X - Y$ plot. Concentration data are often displayed logarithmically on the ordinant (Y) axis, while single components or ratios of compositional data are often displayed linearly on the ordinant axis.

6.3.2.1 For environmental applications such as leak detection along the length of a pipeline or monitoring of contaminant encroachment across a property boundary, soil gas samples are recovered along a profile at intervals from 25 to 100 ft (8 to 30 m) (23). Profiling for natural resource exploration can be performed at sample intervals from 50 to 500 ft (15 to 50 m), depending upon the application.

6.3.2.2 Profiling is useful as a corroborative tool for other monitoring or exploration methods. For example, a soil gas sample profile acquired coincident with a seismic profile can suggest primary contaminant migration pathways or the boundaries of confining layers in shallow, complex geologic settings. This technique has been demonstrated as highly effective in reducing exploratory risk prior to drilling for petroleum and natural gas, by suggesting the presence of hydrocarbon seepage coincident with structures with reservoir potential defined by the seismic method (51).

6.3.2.3 Soil gas profiling is also a convenient methodology effective in comparative evaluation of multiple soil gas sampling techniques. Due to variations common to the dynamic equilibrium conditions over small spatial and temporal intervals in the vadose zone (see 4.1), comparisons of multiple soil gas techniques using only one or a few soil gas samples recovered from nearly identical locations will not result in a valid comparison. However, a visual overlay of soil gas profiles resulting from the implementation of the various sampling techniques can provide a rapid and definitive comparison as to the efficiency of recovery of subject contaminants by a particular sampling system in a specific sampling environment. Similarly, comparison of profiles obtained by using the same soil gas sampling system can provide a direct measurement of system accuracy for quality control purposes.

6.3.2.4 Some investigators compare geographically coincident profiles obtained with the same sampling system at times differing by days or even years in order to generate a data correction factor in order to enhance data comparability. This practice is strongly discouraged. Factors not anticipated in this practice such as the effects of the dynamic equilibrium in the vadose zone, unavoidable changes in procedure due to personnel substitutions, contaminant movement or cultural influence on the sampling environment can have impact on results that are far more significant than the apparent correction.

6.3.3 *Multiple Depth Sampling*—Methodologies encompassing multiple depth sampling normally have one of two goals, that is, to monitor changes in soil gas contaminant fractions versus depth, and to closely follow a single sampling horizon for an entire soil gas grid or profile.

6.3.3.1 When the goal of a survey is to monitor contaminants over varying depths, some sampling systems can recover soil gas samples as probes are advanced deeper into the vadose zone. This practice is helpful in determining the optimum sampling depth for a particular site or to demonstrate the presence or absence of soil atmosphere contamination in a certain horizon. Soil gas contaminant concentrations often increase with depth as the sampling horizon

approaches contaminated ground water or other source of soil gas contaminants (52). Caution must be exercised when soil gas sampling tools are advanced to increasing depths due to the fact that cross contamination of some or all of the sampling system is unavoidable. This situation limits quality control for this type of multiple depth sampling. Attempts to eliminate cross contamination in multiple depth sampling by replacement or decontamination of sampling equipment with each new sample aliquot also result in limited quality control. Tool withdrawal and tool reinsertion result in venting of the sampling environment via an open hole. The open hole behaves as a macroporous pore space, allowing enhanced partitioning into the vapor phase and convective migration to the atmosphere. The end result is a reduction in representativeness for each subsequently recovered soil gas sample.

6.3.3.2 Multiple depth sampling can also be used to focus a sampling program into a single geologic unit or suite of units without regard to depth. This practice is helpful at sites with complex lithologic changes in the vadose zone. Samples can be recovered from lithologies with greater permeability to vapor or greater storage capacity for vapor when bias in sampling depth is necessary to accomplish project goals. This practice involves greater effort and expense than most methodologies due to the necessity to establish the presence, thickness and depth of the target horizons prior to soil gas sampling. The most common application of this methodology is the sampling of soil gas at the top of the capillary fringe.

6.3.4 *Time Variant Methodologies*—Monitoring soil gas in the vadose zone over time can suggest process rates of contaminant partitioning, emplacement, migration and degradation. Practical application of this methodology includes the monitoring of the effectiveness of remedial air-injection systems, the appearance of contaminants sourced from underground storage tanks, the encroachment of contamination onto a subject property from an abutting property and the mitigation of soil and ground-water contamination by microorganisms.

6.3.4.1 Some investigators and regulators with responsibilities at more than one location delegate seemingly simple time variant soil gas monitoring tasks to local personnel. Numerous problems with time variant monitoring can arise in the field as the result of poor system maintenance and record keeping by inexperienced or unmotivated personnel (property owners or parties responsible for contamination).

6.3.4.2 Certain maintenance problems are easily corrected, that is, cleaning bacteria and other foreign matter from detectors or replacing damaged components. Other maintenance problems can be fatal flaws in the methodology. These are principally related to ice formation in the sampling system and destruction of system integrity due to soil frost heaving.

6.3.5 *Combination of Soil Gas Monitoring With Other Vadose Zone Monitoring Techniques*—Soil gas monitoring is not a stand-alone technique. Corroborative support of this reconnaissance and screening tool by other vadose zone monitoring techniques is strongly encouraged. The possible combinations of the various vadose zone techniques with soil gas surveys are numerous. Soil gas can commonly be used as a reconnaissance tool to locate other monitoring devices such as lysimeters, neutron probes or ground water monitoring/sampling wells. Limits upon such combinations are controlled by budgetary constraints and the investigator's imagination.

6.4 *Field QA/QC*—Quality assurance and quality control procedures (QA/QC) are essential to establishing support for any interpretation of measurement data. Soil gas monitoring data requires a thorough QA/QC protocol confirming that data have been generated to satisfy the data quality objectives for the survey. This requirement is well known, however few investigators subject their soil gas data sets to the rigors of such protocol. Conclusions based upon data of unknown quality may be without merit. Justification for interpretations based upon data of unknown quality is not possible.

6.4.1 QA/QC requirements are dependent upon the data quality objectives defined in the planning phase of the survey. For example, simple contaminant audits require a less demanding QA/QC protocol than contaminant source identification. The goals of the QA/QC effort must be understood by field personnel to assure effective implementation of field QA/QC. A document control officer who is a member of the field team can provide this assurance.

6.4.2 Persons collecting descriptive data should not be varied during a soil gas survey. Soil descriptions, for example, can be somewhat subjective when estimations are made as to soil moisture or clay content. Changes in field personnel can translate into apparent changes in soil lithology that are merely functions of this subjectivity. The document control officer can review field records to discover any obvious errors related to descriptive data.

6.4.3 The results of a soil gas survey are highly sensitive to procedure. Field personnel should closely follow a standard operating procedure. This procedure should include the method(s) selected for the survey including the sampling system, means of sample collection, handling and transport of samples and field based equipment decontamination. A standard practice for equipment decontamination is essential to maximize the integrity of samples that may undergo chemical analyses (see Practice D 5088). Any deviations in the standard operating procedure should be recorded by the document control officer in a field notebook, with notes outlining the justification for the deviation. Data comparability can be severely compromised by deviations from the standard operating procedure.

6.4.4 Field based equipment decontamination can have impact on data quality. This results from the potential for cross contamination of samples due to poorly controlled field cleaning procedure or difficulties presented by the inconvenience of field decontamination. Field based equipment decontamination should not be considered a method of choice, but if unavoidable, must be performed with the data quality objectives for the survey as driving forces for procedure.

6.4.5 Bias of soil gas data describes a situation of consistently lower-than-actual or higher-than-actual soil gas contaminant concentration measurements (32). The bias of a measurement process is a generic concept related to consistent or systematic difference between a set of test results from the process and an accepted reference value of the property being measured (see Practice E 177). Bias can be imparted to

the data through sample site selection, that is, exposure of a sampling device to an environment of enhanced contaminant concentration due to a preferential contaminant migration pathway, or exposure of a sampling device to an environment devoid of contaminants due to barriers to contaminant migration. Bias may also result from malfunction of the sampling system, contaminant degradation or numerous other factors. False positive or false negative values can result, lowering the value of the soil gas data set.

6.4.6 Table 2 summarizes some common problems in soil gas monitoring that can result in biased results.

6.4.7 A sampling program must be conducted during the survey to support evaluation of both the sampling system in the field and the analytical system employed. These samples are known as QA/QC samples. The type and magnitude of QA/QC sampling depends upon the purpose of the soil gas survey and the requirements for data quality attendant to it. It is the responsibility of the investigator to determine the appropriate rigor of field QA/QC protocol. The variation in QA/QC protocol from survey to survey is controlled by the purpose and magnitude of the survey, and can vary to a great degree.

6.4.8 The types of field QA/QC samples are field blanks, travel blanks, sample container blanks, sample probe blanks and sample replicates. Other types of QA/QC samples are analytical in nature and are discussed in 6.6.

6.4.9 Field blanks are samples of ambient air or nitrogen recovered from the sampling system which are recovered to determine contamination of samples by ambient atmospheric air, or, to act as system blanks to test for contamination of the sampling system. Field blanks are used to provide an indication of the probability of leakage in the sampling system or the breakthrough of atmospheric air to the sampling device through macroporous migration pathways in the vadose zone such as soil cracks or moldic porosity. If nitrogen is employed instead of atmospheric air, field blanks can have higher contaminant levels than soil gas. This is especially true for petroleum hydrocarbons in urban environments. At least one field blank should be recovered for each ten soil gas samples, or at least one field blank per sample batch or container type (53).

6.4.10 Travel blanks are the contents of a sample container handled in the same manner as those containers holding samples, except that there has been no sample inserted into the travel blank. The purpose for travel blanks is to audit sample integrity for loss due to sample handling and transport. Travel blanks are useful when analysis is performed at an off-site laboratory. The results obtained by analysis of travel blanks can be used to indicate a potential need to modify sample handling and transport procedure. At least one travel blank should be included in each batch of samples.

6.4.11 Sample container blanks are obtained by sampling the contents of a clean sample container to ensure that residual contaminants are not present in the container prior to sample collection. If contamination is detected in the cleaned containers, the decontamination procedure must be modified to remedy the problem. Sample container blanks should be collected and analyzed prior to each use of a sample container.

6.4.12 Sample probe blanks, consisting of carrier gas or atmospheric air contrasted to atmospheric air blanks, are drawn through the sampling device and recovered in the same manner as soil gas. The purpose for sample probe blanks is to check for the presence of sample train contaminants that would impact data quality. If contaminants are detected in sample probe blanks, the decontamination procedure must be modified to remedy this condition. Sample probe blanks should be collected and analyzed prior to each use of a probe and/or other components of the sampling system.

6.4.13 Field replicates are recovered as separate soil gas samples collected from the same sample site into multiple containers. Field replicates can be used to estimate the combined precision of sampling and analysis. The recovery of field replicates is not a common practice. When field replicates are demanded by a client or as dictated by a particular situation, field replicates should be recovered as often as is economically and practically possible, however in no instance should the number of replicates fall below ten percent of the total number of soil gas samples (53).

6.4.14 Sample spiking, or the addition of a known quantity of a known compound or mixture to the soil gas sample, is sometimes performed in the field to provide internal checks of analytical quality. Sample spiking in the field is not recommended due to measurement uncertainties in the field. Moreover, caution must be exercised with this procedure because of the potential for contaminant interaction with the known compound(s).

6.4.15 A paperwork audit is recommended at the end of each working day or at the conclusion of recovery of each batch of samples recovered. The paperwork audit should be conducted by the document control officer and include evidence of an equipment inventory, sample inventory including QA/QC samples, review of field notes and chain-of-custody documentation.

6.4.16 Chain-of-custody documentation is recommended at all times, and is mandatory for soil gas surveys when samples are transmitted to an off-site laboratory. It is recommended for soil gas surveys when sample custody is transferred to someone other than the field team leader for any reason. Chain-of-custody documentation assures that samples have not been altered or mishandled prior to analysis. This procedure is mandatory for sample handling and transport in situations where there is likely to be a cost

TABLE 2 Summary of Possible Causes of False Positive and False Negative Values[A]

Result	Causes
False negatives, that is, falsely low values	Barriers to gaseous diffusion, such as perched water, clay lenses, impervious man-made debris, saturation of soil pores with water (as from rain), low subsurface temperatures.
	Biological or chemical degradation.
	Leakage or blockage in the sample train, improper purge procedure, loss of sample from sample container, problem with analytical system.
False positives, that is, falsely high values	Contamination in sampling train, sample container, or analytical system.
	Contribution of volatile organic contaminants from vegetation.
	Significant contamination in overlying soil.

[A] See Ref (32).

recovery effort or demonstration of contaminant responsibility in a court of law.

6.5 *Sample Handling and Transport*—Soil gas sampling and analysis usually involve the monitoring of contaminants at very low levels. Consideration of sample handling and transport is not trivial to this exercise.

6.5.1 The period of sample handling and transport represents the greatest opportunity for loss or gain of contaminants from or to sample containers. Loss occurs by contaminant condensation within the sampling train, sorption onto materials within the sampling train, solution into condensed water in the sampling train, chemical changes or leakage to the atmosphere through defects in the sampling apparatus or sample container. Gain of contaminants from sources other than the sampling horizon can occur through related mechanisms working in reverse. Both processes can severely limit the value of data obtained from a survey, and they must be minimized.

6.5.2 In general, the time between sample collection and analysis should be minimized. Investigators should protect samples against light and heat, and exercise precautions against leaks (see Practice D 1605).

6.5.3 *Acceptable Materials*—Investigators are responsible for selecting materials for soil gas sampling, transfer and containment that will not impact sample integrity. Containers that have parts made from porous or synthetic materials such as PTFE, rubber or many plastics are likely to retain or contribute contaminants to soil gas samples. Corrosive metals such as steel or brass become difficult to decontaminate upon corrosion due to the increased surface area of the corroded material and its enhanced sorptive capacity. Septa of any material will be responsible for measurable contaminant loss over time due to leakage. Acceptable materials can be conveniently decontaminated prior to soil gas recovery. Materials that cannot be decontaminated effectively between samples must either be replaced between samples, considered in QA/QC planning as a survey limitation or abandoned in favor of more suitable materials.

6.5.4 *Integral Systems*—Problems of sample handling and transport are minimized by integration of the sampling and analytical system. For example, a whole air-active sampling system can be coupled directly to a portable VOC (volatile organic compound) analyzer. The sample stream is fed directly to the intake port of the analyzer and passed through the detector. If there are no system malfunctions in the sample path, problems of sample degradation become trivial.

6.5.4.1 Care must be exercised with integral systems, however. The dead volume of integral systems is much higher than separate sampling and analytical systems. If the sampling system is not capable of delivering constant sample flow rates at or exceeding the requirements of the analyzer employed, data accuracy and comparability can be seriously affected. Moreover, a large sample volume is required merely to purge the sample system. In soils with moderate moisture contents or even nominal clay contents, it may not be possible to recover the volume of soil gas required to purge the system without serious negative impact to the composition of the soil gas sample recovered. Vapor phase contaminants can be lost to purge volume and atmospheric breakthrough can occur, leading toward a false negative result. Although this problem may not be apparent in seriously contaminated environments, it can become a fatal flaw at low contaminant levels.

6.5.4.2 Cross-contamination is a concern with integral systems. Many integral systems employ common elements from sample to sample, namely tubing, flow meters and analyzer components. Overcoming persistent contaminants can be difficult in integral systems, especially when high soil humidity and cold weather complicate the field effort.

6.5.5 *Transfer of Samples from Sampler to Container*—The method of transfer of samples from sampling device to containers is largely dependent upon the volume of soil gas recovered.

6.5.5.1 Small volume samples are commonly recovered by syringe for immediate injection into an analyzer or small volume container. Glass gas-tight chromatography syringes are employed when rigorous QA/QC protocol is required and samples are injected into the analyzer immediately upon recovery. These syringes must be decontaminated prior to recovery of each sample aliquot. Disposable syringes are employed when samples are to be transferred to a small volume container for transport. They are inexpensive, commercially available and convenient to use. However, disposable syringes can present a disposal problem. They should be inventoried prior to use and destroyed after use, the number destroyed equalling the number inventoried and used. Destruction includes smashing the syringe cylinder and clipping the needle.

6.5.5.2 Hand pumps are also used to transfer samples into tedlar bags or glass bulbs. Hand pumps are preferably installed behind the analyzer or container in the sample train to avoid contribution from or loss of contaminants to the hand pump. Hand pumps commonly contain petroleum-based lubricants which will contribute to the hydrocarbon content of soil gas. These devices must be placed at the end of the sample train or abandoned in favor of another tool.

6.5.5.3 Large volumes of soil gas are commonly recovered by hand or mechanical pumps installed at the end of the sample train. Large volume systems can be metered for soil gas flow rate, which is controlled by the capacity of the vadose zone sampling horizon to transmit vapor to the sampling device, the volume and configuration of the sampling system and the requirements of the analyzer or sorptive trap employed.

6.5.5.4 Small volume sampling is quite sensitive to variations in sample transfer technique. Septum coring by syringe is a common problem that restricts flow of soil gas through the needle. Coring can be corrected by decreasing the needle size and using a relatively hard septum material. Coring does not occur with side-port needles, a high-cost alternative. Needles of 25 to 27 gage seldom core septa. However, flow rates through these small gage needles are slow enough to require great care in consistency of sampling rate to minimize septum bleeding during sampling. This consistency is highly subjective and must be obtained through experience. Polypropylene disposable needles may provide opportunity for contaminant loss by sorption or gain by contribution to the soil gas sample. This can be minimized by using the polypropylene syringe to purge the sampling device prior to sampling, thereby reducing the potential for loss or gain of

contaminants to that of the sampling device. Luer-lock needles should be checked for tightness by twisting prior to each use.

6.5.5.5 Tubing is commonly used in large volume sampling. For low level detection, tubing can present a cross contamination problem if not replaced in the sampling train prior to sampling at a new location. Some particulate matter and condensate may be trapped in tubing prior to entry into the flow meter and analyzer by looping the tubing into three or four small diameter loops at a point near the sampling device. This can eliminate the need for water traps or particulate filters in the system that can contribute to system loss or gain of contaminants.

6.5.5.6 Vacuum can be employed to transfer soil gas from a sampler to a container. Evacuated glass bulbs, some containing adsorbents or absorbing liquids (see Practice D 1605), can be affixed to an in-place and purged sampling device and allowed to come to pressure equilibrium. Care must be exercised in recovery of the gas sample from a vacuum cylinder. Upon recovery, the sample is immediately subjected to negative pressure and atmospheric contamination of the sample is encouraged.

6.5.6 *Sample Collection: Containers*—A wide variety of sample containers is employed by field investigators. Container selection is based upon the physical properties of the contaminants sampled, the volume of the sample recovered, the physical properties of suspected contaminants, the sampling system employed, the anticipated sample holding time prior to analysis and the analytical method chosen. Container type for a soil gas survey should be held constant within the survey. A change in container type can impart bias to a portion of the data due to sorptive or desorptive processes related to container type.

6.5.6.1 Whole air samples can be contained in any device made of suitable materials (see 6.5.3) that conveniently satisfy survey, handling, transport and analytical requirements. Certain containers require special handling practice. The literature provides discourse on atmospheric sampling bags (54).

6.5.6.2 Sorbent traps are commonly self-contained. Care must be exercised to select a trapping device that is compatible with the properties of the target compounds and the technique of desorption chosen. Good practice for use of these devices, including handling and desorption procedure is required for successful implementation of sorbent traps when sampling organic compound vapors (see Practice D 3686).

6.5.6.3 Table 2 provides an inventory of sample containers, their applications, advantages and limitations (32).

6.5.6.4 Containers exist that provide for both whole-air and sorbent fractions as well as removal of sample by displacement (see Practice D 1605). Some are convenient for field use, however most are too complex or fragile to be of effective use for a field screening technique requiring rapid mobility.

6.5.6.5 Detector tubes should not be considered as a primary containment vehicle for the purpose of storage and transport of soil gas. A discussion of detector tube application is provided in 6.6.1.

6.5.6.6 Containers for soil samples to be preserved for a subsequent headspace analysis range from glass sample vials to metal cans. The choice of container for soil headspace determination is dependent upon the method of sampling chosen. For soil samples obtained by backhoe, bucket auger or other destructive technique, that is, a disturbed sample, extrusion into a sample vial is not necessary since most of the highly volatile components have already been lost through the act of soil sampling. Metal cans should be made from a material that does not rust. Coating materials and sealing waxes are likely to react with or adsorb soil contaminants, presenting limitations to the value of the data collected. Glass containers with screw threads or crimped seals are difficult to use for soil headspace methods due to the inability of investigators to consistently, thoroughly and rapidly clean the threads or crimp surfaces of all containers prior to capping.

6.5.6.7 Soil pore liquid headspace samples are whole-air or whole-air plus pore liquid samples. They may be contained in most devices suitable for whole-air containment, however investigators are cautioned to select containers from which a vapor sample can be extracted for analysis independently of the liquid present.

6.5.7 *Sample Processing*—Some investigators process soil vapor samples prior to analysis. Processing is performed in an effort to control sample degradation in containers. Efforts to check this degradation by sample processing include refrigeration, pressurization, and pasteurization. As a general practice, sample processing is strongly discouraged. Refrigeration may be somewhat effective in controlling sample degradation, however the best method is to limit or avoid soil gas sample storage whenever possible. The limited shelf life of soil gas samples is discussed in 6.5.9.

6.5.7.1 Extraction is a sample processing step used to remove soil contaminants from soil cores or other similar samples. This technique can efficiently recover contaminants from all residence phases, not just the vapor phase. As a result, the technique yields samples that are not representative of soil atmosphere contaminant suites.

6.5.8 *Sample Transport*—If samples are to be transported to an off-site laboratory for analysis, they must be properly packaged to avoid damage to sample containers. Care must be taken to keep samples from becoming overly warm or agitated during transport. Overnight air express is highly convenient if samples are properly contained, but air freight is not recommended if samples are held in containers such as gas tight syringes or tedlar bags. These containers have other limitations as discussed in 6.5.6.

6.5.9 *Sample Life*—Soil gas samples have limited shelf life even in the most effective containers. Soil gas sample life is strongly container dependent. Numerous factors limit shelf life; most involve degradation in a container. Exposure to light, heat and agitation during shipping will accelerate sample degradation. Biodegradation may occur in some sample containers if water vapor condenses in a container containing microorganisms capable of metabolizing contaminants as substrate.

6.5.9.1 The safest practice is to minimize sample storage time. This problem is greatest when off-site laboratories are engaged to analyze the samples. Prior to recovering the soil gas samples, arrangements can be made with the selected off-site testing laboratory to schedule the necessary personnel and equipment in anticipation of sample delivery.

6.5.10 *Soil Gas Archiving*—Sample archiving in anticipation of a future analytical or descriptive requirement is a common practice. Minimal effects of degradation or loss may be noted in storing certain sorbed samples. Soil gas archiving is, however, not recommended. Although dependent upon the type of container and the storage environment, the likelihood of degradation of soil gas samples is great enough to raise concern. Insertion of standard gases into an archived sample set and spiking of archived soil gas samples with standards provides a reference to determine the likelihood or extent of sample degradation.

6.6 *Analysis of Soil Gas Samples*—Soil gas analysis procedure is based upon pre-existing protocol established for the analysis of contaminants in ambient air. A common reference practice defining terms, sampling information, calibration techniques and methods for validating results may be applied to all automatic analyzers (see Practice D 3249). Basic laboratory practice common to investigators engaged in sampling and analysis of atmospheres applies to soil gas analysis. Note that air sampling protocols and soil gas sampling protocols are not equivalent; geophysical and geochemical factors as well as definition of air sample volume contribute to this lack of equivalency. This guide includes the criteria, guidelines and recommendations for analytical segments including the mode of operation of the laboratory and data validation (see Practice D 3614).

6.6.1 *Basic Analytical Approach*—Soil gas analysis is performed to identify the presence of contaminants, their type and relative concentrations. Various analytical methods are highly general, satisfying only the most rudimentary requirements of contaminant screening. Others are sophisticated, providing identification and relative concentration information for numerous chemical compounds determined to be present in a soil gas sample. The choice of basic analytical approach in soil gas analysis is driven by the purpose of the soil gas survey, quality assurance objectives and budgetary constraints placed upon investigators.

6.6.1.1 Soil gas surveying as a field screening technique can often be effective without the commitment of expenditure for highly sophisticated techniques. This survey purpose is merely to locate other, more direct, techniques. Caution is suggested when choosing highly sophisticated analytical methods for field screening by soil gas monitoring. This selection is controlled largely by the need for the analytical method chosen to be cost-effective.

6.6.1.2 Other applications of soil gas monitoring require more thorough analytical protocol. It is not possible, for example, to suggest the locations of partitioned miscible and immiscible ground-water contaminant plumes with elementary analytical systems. Moreover, the independent monitoring of multiple classes of contaminants in soil gas normally requires analytical systems with multiple detectors. Successful soil gas monitoring for petroleum exploration requires an analytical system which can separate and identify extremely similar volatile compounds occurring at very low concentration levels.

6.6.1.3 Contaminant concentrations in soil gas can vary from levels below the detection limit of the most sophisticated equipment to percent of a whole-air sample. Ideally, the analytical system chosen has enough flexibility to determine contaminants in a wide range of concentrations. Care should be taken to select an analytical system sensitive enough to avoid false negative results which can lead to invalid conclusions. Many analytical systems are not designed to perform to specifications in very high concentration environments, requiring sample dilution prior to analysis or selection of a less sensitive method.

6.6.1.4 Of primary importance to the successful analysis of soil gas is the familiarity and experience of the analyst with the analytical system chosen. The analyst must be able to independently care for and maintain the equipment as well as recognize symptoms of procedural error. The success of an analytical effort lies wholly with operator ability and experience. Excessive machine capability cannot compensate for operator inexperience.

6.6.1.5 Soil gas may be analyzed by a number of methods, including portable VOC (volatile organic compound) analyzers, gas elution chromatography, gas chromatography-mass spectroscopy, and colorimetric and color-indicating detector tubes. Infrared spectroscopy and fiber optic chemical sensors can be applied to soil gas gas analysis, however their use is currently limited and few investigators have experience with this instrumentation. In practice, gas chromatography (GC) or GC-based handheld detectors are the most widely used analytical instruments (32) for soil gas analysis. This guide uses numerous terms relating to various GC methods for soil gas analysis. Most of the terms should apply to other GC methods (see Practice E 355).

6.6.1.6 Portable VOC analyzers used for fugitive emission screening and industrial hygiene monitoring have been adopted for soil gas analytical purposes by numerous investigators. These devices are easily transported to and from the field, require minimal operator skill, provide immediate data and serve to eliminate many sample handling and transport steps which can result in uncertainty. Portable VOC analyzers are limited in application to very low level detection due to the absence of a concentration step. They exhibit limited selectivity and do not have the ability to separate contaminant compounds, leading to potential interference. These devices also are limited in accuracy due to the inability to calibrate for the wide variety of contaminant compounds encountered in soil gas, each compound having its own character of detector response. Portable VOC analyzers contain three types of detectors. These are the flame ionization detector (FID), the photoionization detector (PID) and the infrared (IR) detector. The literature contains a thorough treatment of these devices (10, 55).

6.6.1.7 Soil gas analysis by GC is by far the most versatile and the most costly soil gas analytical method. Instrumentation can be varied to accommodate field mobility, however this is not always required. The technique provides separation of compounds in a chromatographic column, tentative identification of compounds determined to be present and a relative quantitation of compound concentration based upon comparison to a known standard. Soil gas is introduced into the GC and conveyed through a chromatographic column by a carrier gas, separating the contaminants as they pass through the column. The separation is obtained when the sample mixture in the vapor phase passes through a column containing a stationary phase possessing special adsorptive properties. As the gas stream emerges from the column, it passes through a detector, providing for measurement of a

specific sample property through the recording of detector electrical response. These responses, or peaks, are recorded as a function of time. Comparison of known standard compound response time with the response time of an unknown represented by a peak results in the tentative identification of the unknown. Comparison of the magnitude of detector response to the newly identified compound versus detector response to the same compound of known concentration, a laboratory standard, results in a relative quantitation of subject compound concentration in the sample.

6.6.1.8 Gas chromatography is essentially a physical separation technique. The degree of separation depends upon the differences in the distribution of volatile compounds, organic or inorganic, between a gaseous mobile phase and a selected stationary phase that is contained in a tube or GC column (see Practice E 260).

6.6.1.9 Numerous factors can impact the ability of the GC to determine contaminants in a soil gas sample. These include column characteristics, sample flow rate, sample temperature, the composition of the carrier gas and the type of detector employed. Instrumentation can be expanded to include multiple columns, multiple detectors, sample loops and temperature programming, all of which make an instrument more versatile, albeit at additional cost.

6.6.1.10 Simple GCs are portable analyzers with GC options. Field GCs are more advanced instruments with temperature programmable ovens and provide opportunity for multiple columns and detectors. They can be carried in mobile laboratories or established in a temporary base laboratory in the field. Research-grade instruments are normally based at off-site laboratories with strictly controlled environments. These are used when positive identification or very low detection limits are specified. The literature contains excellent comparisons of the advantages, limitations and applications of the various configurations of GCs, including instrument specifications (**10, 32, 56, 57**).

6.6.1.11 Detector tubes have been applied to safety and health atmospheric monitoring, agriculture and the chemical industry. These devices are designed to be compound specific, although this characteristic is dependent upon the contaminant compounds present in the sample drawn through the tube. Detector tubes may be used for short-term sampling (grab sampling; 1 to 10 min) or long-term sampling (dosimeter sampling; 1 to 8 h). Short-term sampling involves the movement of a given volume of gas through the tube by a mechanical pump. If the substance for which the detector tube was designed is present, the indicator chemical in the tube will change color (stain). The concentration of the gas may be estimated by either the length of the stain compared to a calibration chart or by the intensity of the color change compared to a set of standards (see Practice D 4490). Long-term sampling involves the movement of gas at a very slow rate through the tube by means of an electric pump. The use of long-term detector tube sampling for soil gas monitoring is limited to specific temporal survey designs.

6.6.1.12 Detector tubes are relatively inexpensive and provide immediate results. Their use is restricted to applications with few interfering compounds. Depending upon the contaminants present, they may be of low sensitivity and can be affected by humidity, normally high in soil gas, sample flow rate, temperature extremes (32), storage conditions and shelf life.

6.6.1.13 The literature contains excellent discourse on the detector tube apparatus, reagents, procedure accuracy and amenable compounds (see Practice D 4490).

6.6.2 *Specific Analytical Approaches*—This subsection discusses various detectors and methods that may be integrated into soil gas analytical instrumentation. For methods providing detector alternatives, the choice of an appropriate detector should be guided by knowledge of detector properties. Key properties are as follows (after Mayer, 1989 (32)):

6.6.2.1 *Selectivity or Specificity*—Selectivity refers to the responsiveness of the detector to the compound of interest. Detectors responding to a wide range of classes of compounds are termed universal or non-selective detectors. Those that respond to only certain classes of compounds are termed selective detectors.

6.6.2.2 *Sensitivity*—Sensitivity refers to the relationship between the detector response and the quantity of the subject compound injected. It is the smallest detectable quantity of a compound; it is usually considered to be the amount that produces a response equal to twice the baseline noise of the detector.

6.6.2.3 *Linear Dynamic Range*—Linear dynamic range is the range over which the detector response to a compound is directly proportional to the amount of compound injected. Detectors vary in the range of component concentrations over which they are linear. Wide linear dynamic range is desirable because it simplifies quantitation of samples having widely varying ranges of concentrations.

6.6.2.4 *Stability*—Stability is a factor referring to detector responsivity over time. Stability is controlled by numerous factors and is seldom quantified. The required frequency of instrument calibration is determined by detector stability.

6.6.3 Specific analytical approaches are as follows:

6.6.3.1 *Flame Ionization Detectors (FID)*—Flame ionization detectors generate electric current when gases containing carbon atoms are oxidized to carbon dioxide in a hydrogen flame and potential is applied across the flame. The magnitude of the electric current generated is termed the detector response. FIDs are responsive to hydrocarbon contaminants in soil gas and are commonly employed for this purpose. These detectors are durable for field application, and have a wide linear range and nearly uniform response to organic gas species. FIDs are generally unresponsive to inorganic gases and water vapor, common constituents in soil gas. FID performance can be evaluated independently of the chromatographic column (see Practice E 594). Although highly versatile, these detectors are not selective for halogenated compounds. They require supplies of fuel gas which require careful safety practices in handling and flame ignition.

6.6.3.2 *Photoionization Detectors (PID)*—Photoionization detectors employ ultraviolet radiation to ionize contaminant molecules. Positive ions and free electrons are formed which migrate to the detector electrode(s), resulting in an electric current that is proportional to contaminant concentration at the detector. PIDs are extremely sensitive to aromatic hydrocarbons due to the great efficiency of ionization of pi bonds under ultraviolet radiation. Efficiency of ionization of sigma bonds is lower, resulting in a higher PID detection limit for aliphatic hydrocarbons. The selectivity of

the method can be adjusted by selecting lamps of different energies, causing a change in response of contaminants with fixed ionization potentials to changing lamp energies. Tables exist of ionization potentials of compounds within classes common to soil gas contaminants (58). Methane has an ionization potential higher than the energies of commercially available lamps, limiting the PID to detection of compounds other than methane. PIDs are further limited by their tendency to conceal the presence of low-sensitivity compounds when high-sensitivity compounds (aromatics) are present. PID response can be impacted by condensation of water vapor in the lamp.

6.6.3.3 *Electron Capture Detectors (ECD)*—Electron capture detectors are highly sensitive to and selective for compounds with electronegative functional groups such as CFCs (chloro-fluorocarbons). The sensitivity of the detector is proportional to the number of these groups on a compound, resulting in a unique detector response to each compound. The ECD comprises a source of thermal electrons inside a reaction chamber (a radioactive source emits β radiation which ionizes the carrier gas to produce electrons). The device detects compounds with electronegative functional groups capable of reaction with thermal electrons to form negative ions. Such reactions cause a decrease in the concentration of free electrons. The detector is designed to measure changes in the concentration of these electrons inside the chamber (see Practice E 697). Calibration of the ECD is therefore linked to each compound to be determined by the detector. ECDs are also sensitive to water, oxygen and other common components of soil gas, causing potential problems in method performance. ECDs emit β radiation that should be properly vented. Operation of an ECD requires licensing under Federal regulation.

6.6.3.4 *GC/Mass Spectroscopy*—Combination of gas chromatography and mass spectroscopy results in the GC/MS method of analysis. A mass spectrometer is used to obtain a mass spectrum of each eluting compound. Positive identification of these compounds is sometimes obtained by comparison of the unknown mass spectrum to a library of known spectra. GC/MS can be extremely selective for target compounds. Use of the technique for soil gas monitoring is limited, primarily due to the cost of analyses.

6.6.3.5 *GC/Fourier Transform Infrared Spectroscopy*—This analytical method combines gas chromatography with Fourier transform infrared spectroscopy. GC/FTIR can provide a rapid identification of eluting compounds by comparison of their infrared spectra with a known spectral library. Quantitation is achieved by subsequently passing the sample through an appropriate GC detector such as the FID or ECD. This method, like GC/MS, is limited in application to soil gas monitoring by the high cost of analysis.

6.6.3.6 Other detectors are applied to soil gas analysis by GC, albeit rarely in comparison to FID, PID and ECD. They include the argon ionization detector, a non-destructive device similar in operating design to the ECD, the flame photometric detector (FPD) used to determine organic compounds containing sulfur and phosphorus, and the hot-wire (pyrolyzer) used to determine compounds containing nitrogen.

6.6.4 *Analytical QA/QC*—The validation of the analytical aspects of soil gas monitoring is fundamental to the technique. Analytical equipment and procedure must be evaluated by laboratory QA/QC, just as the sampling system, sampling plan and field procedure are evaluated by field QA/QC methods. Analytical QA/QC defines a confidence limit of performance. The utilization of well tested and uniform analytical practices is essential to the production of reliable and defensible data, the validity of which can be demonstrated at a later date through the use of written field and laboratory records (see Practice D 3614).

6.6.4.1 Most analytical QA/QC plans contain calibration steps, linearity checks, standard analyses, blank analyses, duplicate analyses and audit checks. The various analytical approaches discussed in 6.6.3 require a variety of different protocols which will satisfy the QA/QC requirements for each method. Four types of analytical QA/QC samples are required for determination of quality assurance. These are analytical reagent blanks (used to determine the potential of sample or standard contamination from a reagent), laboratory blanks (used to determine the impact potential of the laboratory atmosphere on analytical results), analytical sample replicates (used to estimate the analytical precision for samples) and analytical standard replicates (used to estimate the analytical precision for standards). Table 3 provides a summary of suggested calibration and quality control requirements for analytical systems (10).

6.6.4.2 The aspects of bias, precision, representativeness, completeness and comparability must be considered to evaluate analytical equipment performance, including the establishment of minimum detectable quantities of contaminant compounds, retention time drift and the linearity of instrument response. Bias and precision must be quantified in order to compare actual survey performance with goals established in the survey plan.

6.6.5 A data validation summary report is a common method of evaluating analytical system performance. A guide for determining parameters key to the data validation summary report is provided as follows.

6.6.5.1 *Bias*—For determination of bias, the percent recovery can be determined using the following formulas:

$$recovery\ reproducibility = (DCS/KCS)*100 \quad (6)$$

where:

DCS = determined concentration of standard, and
KCS = known or certified concentration of standard.

The standard deviation of all standards analyzed can be determined as follows:

$$SD = \{(sum(recovery\text{-}i - recovery\text{-}ave)^2)/(n-1)\}^{0.5} \quad (7)$$

Finally, the range of uncertainty can be determined using the following equation:

$$\pm R = \pm t*(SD)/(n^{0.5}) \quad (8)$$

where:

t = the value of Studentized t at the 90 % confidence level and $(n - 1)$ degrees of freedom.

The bias statements for data collected should be expressed as the average recovery plus or minus the range.

6.6.5.2 *Precision*—For the determination of precision, the relative standard deviation of replicates can be calculated using the following equation:

$$RSD\text{-}pair = SD/Mean \quad (9)$$

TABLE 3 Soil Gas Sampling Containers[A]

Type	Applications	Advantages	Limitations
Stainless steel canisters	Collection of samples for delayed analysis	Durability Ease of sample handling Can be re-used Sample holding time longer than that for other whole-air sample containers Sample volume measurement not required Desorption not required Allows replicate analysis	Expense Requires vacuum pump or gage Can be difficult to decontaminate
Glass bulb	Collection of samples for delayed analysis	Glass is more inert than other sample container materials Septa possible Allows replicate analyses	Easily breakable Leakage through stopcocks or septa possible Adsorption to PTFE or other parts
Bag	Collection of samples for delayed analysis Sampling of very high vapor pressure compounds for which absorption methods are unsuitable	Bulk loss of sample is readily apparent Containers are light-weight and easy to handle Sample volume measurement not required Desorption not required Allows replicate analyses	Expense Some compounds may be lost through or adsorbed to bag walls Some container materials may contaminate samples Containers cannot be easily re-used Leaks in valves
Syringe[B]	Collection of samples for on-site analysis	Ease of sample collection Does not require special equipment to introduce sample into GC Desorption not required	PTFE plungers can adsorb sample Holding time short due to leakage or absorption Sample volume smaller than for other containers
Sorbent sampler	Allows concentration of low level samples If samples are solvent-desorbed, allows analysis of liquid sample	Ease of handling Relatively long holding time	Requires precise sample volume measurements Sorbent type must be tailored to compounds to be measured; adsorption behavior of each compound for solvent used must be accounted for Requires desorption (thermal or solvent) for analysis

[A] See Ref (32).
[B] Syringes may also be used to transfer samples from the sampling device to a container for off-site analysis.

$$RSD\text{-}ave = \{\{(sum(RSD\text{-}pair))^2\}/(n-1)\}^{0.5} \quad (10)$$

where:
RSD-pair = relative standard deviation for each pair of replicates, and
RSD-avg = relative standard deviation overall.
Next, the precision can be determined as follows:

$$precision = \{(t*RSD\text{-}avg)/DF\} *100 \quad (11)$$

where:
precision = the percent precision,
t = the *t* value for $n-1$ pairs of replicates, and
DF = the degrees of freedom = $(n-1)$.
Finally, mean value is reported with associated uncertainty:

$$x \pm (x*t*SD\text{-}ave)/(DF)^{0.5} \quad (12)$$

where:
x = reported chemical concentration, and
t = the value of *t* at the 90 % confidence level for the appropriate degrees of freedom.

6.6.5.3 *Representativeness*—Representativeness is determined by the results of the cross contamination blanks and the air blanks. The results should be presented as a bias estimate, as follows:

$$bias\ (\%) = \{(CCC - CA)/Mean\} *100 \quad (13)$$

where:
CCC = concentration in cross contamination sample,
CA = concentration in air, and
Mean = mean concentration in sample set (bias may also be expressed for a single sample by substituting sample concentration).

6.6.5.4 *Completeness*—The completeness goal is 90 % or higher. Completeness is the number of samples collected that can be validated through the procedures for bias, precision, and representativeness.

6.6.5.5 *Comparability*—Comparability is based upon professional judgment and is provided through planning steps carried out prior to initiation of field work.

6.7 *Data Interpretation*—Soil gas data interpretation is an iterative process including the examination of the raw data, selection of appropriate and useful data displays, and establishment of correlation of the data set to other vadose zone monitoring data and ground truth. Interpretation of soil gas data is not like other interpretive exercises involving measurement data, in that mathematical expressions relating soil gas contaminant concentrations to underlying soil, rock and ground-water contaminant concentrations cannot be written for most applications at a high confidence level. This is a function of a lack of site characteristics information at even the most comprehensively studied sites. Soil gas data cannot be consistently interpreted in a manner that establishes direct correlation between contaminants in a soil gas horizon and contaminants in other horizons. Processes including migration and degradation can have profound influence on the correlation of soil gas data to ground truth. Interpretive efforts excluding consideration of these influencing processes can be highly misleading. For example, the presence of contamination in an underlying horizon will not necessarily correlate to the detection of contaminants in overlying soil atmospheres, that is, the potential for a false negative result. The converse is also true, that is, the potential for a false positive result. Interpretation of GC results in the laboratory without consideration of pertinent hydrogeological informa-

tion may lead to incorrect conclusions (59). However, the detection of contaminants in soil gas does suggest the existence of a contaminant source, and increases in contaminant concentration can suggest close proximity to the source or an increased quantity of the subject contaminant in the subsurface. It is the responsibility of the interpreter to examine soil gas data in context of other site characteristics, and provide an interpretation based upon sound judgment and thorough yet practical data treatment.

6.7.1 *Manipulating Data*—Soil gas data is normally interpreted as raw data. The application of correction factors is not recommended, as it is difficult if not impossible to determine if the magnitude of the correction factor is greater than that of the variance between data populations in a survey. Moreover, the need for correction factors can indicate a flaw in survey design, sampling system performance or the objectivity of the interpreter.

6.7.2 *Defining Data Subpopulations*—Soil gas monitoring seeks to define anomalous subpopulations of data that contain measurable quantities of contaminants or unusual compositions. These populations can easily be described by their contrast to normal populations, for example, contrasting populations with and without measurable contaminants. Establishment of contaminant baselines or conditions "at background" make this contrast possible. If all soil gas samples are recovered in a contaminated area, there may be no apparent contrast.

6.7.2.1 Statistical treatment of soil gas monitoring data allows the interpreter to estimate the amount of variation noted in the survey data due to errors. This practice also permits the interpreter to evaluate the data quality objectives suggested for the survey during the planning phase. Statistical treatment of soil gas data can also be of use to define anomalous data subpopulations when the boundaries of a contaminated area are not clearly defined or if the existence of multiple populations of data (that is, contaminated and uncontaminated) within a single data set is in doubt. The literature contains discourse on statistical treatment of soil gas data (10, 60).

6.7.3 *Interpreting Soil Gas Data Profiles*—Soil gas data from survey profiles displayed on an $X - Y$ plot is an effective aid to data interpretation. This display is useful to examine the overall context for soil gas measurement data potentially indicating contamination. If the profile is displayed as a cross section through a grid pattern or as a linear array of sample points, the profile display can illustrate spatially significant groupings of data subpopulations.

6.7.3.1 It is quite common for concentration data to be highly variant within a contaminated area. Soil gas profiles can be used to show variation in spatially related data. This is one method of defining subpopulations of data indicating contamination or other anomalous characteristics.

6.7.3.2 Multiple data sets can be displayed on a single profile. Comparison of one data set to another on a single profile is a simple visual method to screen for suggested data subpopulations. Comparison of concentration data and compositional data (see 6.7.5) on a single profile can further resolve this problem.

6.7.4 *Mapping Soil Gas Data*—Soil gas data obtained by sampling at a single depth is often mapped to suggest the lateral extent of subsurface contamination. Map suites of soil gas data obtained from multiple depths can sometimes aid investigators in determining the depth to the contaminant source.

6.7.4.1 Numerous algorithms can be used to interpolate between data points, including linear, inverse distance squared, inverse distance cubed, splines and kriging. The various interpolation methods will yield similar results, suggesting a general pattern of contaminant distribution in soil gas. Kriging requires a probability model for each survey site mapping application for which it is employed, the derivation of which requires data which are not normally available for a given soil gas survey area.

6.7.4.2 Caveats exist in using computer mapping programs as interpretive aids. Difficulties can arise in treatment of adjacent data points differing in contaminant concentration by an order of magnitude and more due to vapor migration barriers, preferential vapor flow paths or changes in soil moisture or porosity content. It is possible to model these characteristics and input such a model into some computer mapping programs, however this introduces bias into the mapping effort. Single point soil gas contaminant concentration highs may exist due to a sample density which is insufficient to resolve the cause for the single point anomaly. Contour mapping of such data may be meaningless without the complement of other information, especially detailed knowledge of site characteristics.

6.7.5 *Analyzing the Composition of Soil Gas Contaminants*—Certain applications of soil gas monitoring require detailed analyses available from off-site bench laboratories or mobile laboratories. Determination of a number of contaminant compounds in a soil gas sample set with either of these analytical systems enables the interpreter to make a comparative analysis of the changes in soil gas contaminant composition within that sample set.

6.7.5.1 Compositional analyses can range in scope from a simple listing of the various compounds determined in each sample to thorough data treatments. Profiles of soil gas data can be constructed to illustrate the spatial relationship between two potentially different groupings of data (see 6.7.3). Crossplots of contaminant compound concentrations are highly effective in the definition of data subpopulations, and can be used to relate contaminant types to known on-site waste streams and sources in complex settings. Known as fingerprinting, this guide compares vapor composition over a known contaminant product and the known soil atmosphere composition over that product to soil gas contaminant composition in areas being investigated on the subject site. Subtle divisions in data subpopulations can be defined by crossplots of contaminant ratios. In addition to simple ratioing, computerized multivariate pattern recognition techniques such as cluster, factor and discriminant analyses can assist in the evaluation of intra-data set compositional variations and their relationship to the physical contamination issues at a site.

6.7.5.2 Soil gas data can be examined for the appearance of target compounds determined to be present in contaminant mixtures. The success of this practice, used primarily to establish the location and extent of underlying ground water contamination, relies upon selection of appropriate target compounds and the persistence of target compounds in soil vapor.

6.7.5.3 Monitoring specific compounds in soil gas data can be utilized to determine the progress of degradation or migration of contaminants in the vadose zone and in ground water. Biodegradation has been monitored by the appearance of excessive quantities of carbon dioxide in soil gas (61).

6.7.6 *Interpretation in Context of Other Vadose Zone Monitoring*—Soil gas monitoring is not a technique that can consistently support conclusions based upon interpretations of survey results. For this reason it is strongly recommended that other vadose zone monitoring methods be used to corroborate data obtained from a soil gas survey, especially when investigators are attempting to do more than simply audit a subject site for the presence of contaminants. Useful models of contaminant emplacement and transport in the vadose zone can be constructed by combining techniques. Examples of useful combinations are soil pore liquid and soil gas monitoring or neutron probe and soil gas monitoring.

6.7.7 *Correlation With Ground Truth*—Interpretation of soil gas data is difficult without establishing some form of ground truth with which to substantiate survey results. Ground truth can be in the form of monitoring well data, for purposes of determining the extent of contamination by a ground-water contaminant plume. Examples of other forms of ground truth usable in support of soil gas data interpretation are soil cores, the presence of contaminant odors in basements, observed floating contaminants in storm sewers or utility vaults, or other field observations.

7. Data Reporting Requirements

7.1 *Purpose of Reporting*—Of primary concern in a report of findings pertaining to a soil gas survey is that the report includes the information necessary to describe the results of that survey performed for a particular application. In many instances, certain interpretative methods or data reporting formats useful to end users for one particular application are not relevant to the needs of end users applying the information to a different application. Examples of these differing applications that require unique report subject matter are soil gas contaminant determinations for real property environmental assessments, soil gas monitoring of volatile organic contaminants from underground storage tanks and soil gas sampling as a tool useful in the exploration for natural resources. Certain applications require a thorough treatment of a significant number of factors impacting the meaning and usefulness of soil gas data interpretations. Examples of such applications include damage assessments, contaminant source identification or tests of the effectiveness of remediation. Other applications command minimum reporting requirements. An example of such an application is the monitoring of releases from underground storage tanks over time. Included in a discussion of the report objectives should be an identification of the end user category (for example, regulatory agency, land acquisition negotiations).

7.1.1 A decision must be made regarding the units expressed in reporting, that is, qualitative or quantitative. If quantitative, the appropriate expression of units in volume/volume or weight/volume must be determined. SI units are recommended for reporting of atmospheric measurement data (see Practice D 1914).

7.2 *Report Format*—Certain reporting requirements are commanded without regard to data application. In large part they are related to the QA/QC objectives, and include data comparability, representativeness, bias, precision accuracy, completeness and analytical detection limits whenever possible. At a minimum, a general discussion of the reliability of results and analytical detection limits is warranted; soil gas test data may be evaluated in the same manner as is other atmosphere test data (see Practice D 3614).

7.3 *Salient Points to be Addressed in Reporting*—The report of findings of any soil gas monitoring effort can contain discussions within any number of topics that should be selected to best suit the requirements of the end user. Selection of appropriate topics is discretionary, usually based upon a scope of work determined by prior agreement between the data provider and the data end user. Efforts to limit reporting requirements for the sake of short term time and money cost savings usually result in low-confidence level treatment of the report or an ultimate time and money cost gain, or both. Discussions that should be included when appropriate and whenever possible are provided below.

7.3.1 The purpose of the soil gas study should be stated, as well as the rationale for selection of a particular soil gas monitoring technique.

7.3.2 Selection of a particular soil gas monitoring technique is typically controlled by the chemical and physical properties of the chemical compounds of interest which are known to occur or suspected to occur on site. A discussion of the sample array in three dimensions, sampling method employed and the analytical scheme chosen in context of these properties should be provided.

7.3.3 The rationale for selection of a particular soil gas monitoring technique should always be based upon the physical properties of the vadose zone as well as the chemical and physical properties of the compounds of interest. A discussion of the impact of these vadose zone properties on survey design should be included in the report. The regional and local hydrogeologic conditions within the survey area should be described. A discussion of the regional geology should include the physiographic province, a generalized geologic column, geologic structure and general ground water occurrence. The local conditions should be described with regard to soil type(s), moisture content in the vadose zone, soil/bedrock interface, stratigraphy and lithology, ground water bearing zones, flow directions and gradients, potentiometric levels, aquifer characteristics and ground water quality.

7.3.4 If known and appropriate, the characteristics of a contaminant source or spill should be addressed. Examples of such characteristics are contaminant composition, the likelihood of single or multiple contamination events or the reaction potential (above, within and beneath the vadose zone) of multiple contaminant mixtures.

7.3.5 Every subject of every vadose zone monitoring effort has unique characteristics. Those characteristics that could impact the results of the soil gas monitoring effort should be described to provide a meaningful context in which to interpret the soil gas data.

7.3.6 There are a number of topics common to most soil gas data reporting that are useful in the majority of applications. The regional and specific site location should be identified using a site plot plan. The site plot plan could include an insert showing the regional location. A discussion

should be included regarding the physical structures at the site that may impact the location of sampling points and the migration of soil gas, for example, asphalt and concrete pads, buried pipelines and surface water impoundments. Site history must be considered, including the types of chemical compounds known or suspected to have been used at the site. These compounds should be listed with their chemical and physical properties as they relate to volatilization, solubility and other migration characteristics or soil gas recovery characteristics.

7.3.7 The site should be evaluated in the report of findings for the impact of the regional and local hydrogeologic conditions within the survey area on the results of the survey.

7.3.8 A detailed description should be given of the type of soil gas survey conducted. Details should include selection of active or passive method, whole air or passive sample collection method, sampling array, background sampling, equipment decontamination procedure employed prior to the survey, field or laboratory analytical methods and QA/QC procedures. Any unusual conditions should be noted, such as rainfall events during the course of the survey (especially when moveable soil gas chiefly originates from vadose zone microporosity), high pressure or low pressure front movement across the survey area during the course of the survey (especially when moveable soil gas chiefly originates from vadose zone macroporosity), or visual observations of contamination at sampling points.

7.3.9 If a subject property is found to be contaminated, a separate discussion of soil gas characterization of uncontaminated or non-anomalous contiguous property should be provided in the report of findings. This can be useful in highlighting naturally occurring petroleum hydrocarbons in soil and in establishing a regional baseline of contamination.

7.3.10 Data collected during the field sampling and field or laboratory analyses should be compiled in table form and be included in a preliminary or final report, preferably as appendices. Such data should include a listing of sampling and analysis dates, soil/rock description at each sampling point, depth and diameter of sampling point, quantity of soil gas purged prior to sampling, quantity of sample extracted, chromatogram and/or mass spectra for each sample and a tabulation of QA/QC samples recovered.

7.3.11 The report of findings should include a discussion of the results of the QA/QC efforts, establishing performance within limits set prior to the survey. Data validation involves review of the data collected for the purpose of isolating spurious values (32). Systematic errors or bias can be detected in this review. Suggestions should be made as to the origin of the errors or bias.

7.3.12 Results of analyses should be displayed on plan maps and should include sampling point locations, physical features, contours of equal concentrations of specific compounds or compound groups (for example, alkanes) and any necessary keys or other notes to guarantee map clarity. Cross-sections showing changes in contaminant concentration with depth and concentration profiles of more than one contaminant through several sample locations can be highly useful displays. The report should include text describing each map, cross-section or profile.

7.3.13 Whenever possible, discussion should be provided that correlates soil gas data to ground truth. The most common and widely accepted form of ground truth is data from ground water monitoring wells.

7.3.14 When appropriate, the report of findings should attempt to identify the source of the contaminants encountered in the soil gas survey.

7.3.15 The report should contain a section which discusses the conclusions drawn from the results of the soil gas study and any recommendations which seem appropriate to enhance the value of conducting such a soil gas study. Conclusions should include identification of the compounds detected, if any, an assessment of the appropriateness of the soil gas study method used, and any circumstances that may have significantly impacted the results of the investigation, such as weather conditions or equipment calibration. Recommendations should address need for establishing ground truth, extension of the study to adjacent areas of interest, the need for a different soil gas study method, actions to resolve questionable QA/QC results, or need for additional chemical analyses for contaminant identification.

7.4 *Disadvantages of Real-Time Reporting*—In actual practice, many end users request real-time reporting of soil gas data obtained from field-based laboratories. Presentation of such data presents the opportunity for misunderstanding by end users who are not familiar with the caveats presented by data not examined in light of the QA/QC program or site specific factors. Real-time reporting of soil gas data is therefore not recommended.

8. Keywords

8.1 contaminant; environmental monitoring; geochemistry; ground water; Henry's law; petroleum hydrocarbon; sampling; soil gas; unsaturated flow; vadose zone; vapor monitoring; volatile organic compound

TABLE 4 Summary of Suggested Calibration and Quality Control Requirements for Analytical Systems[A]

Type of Instrument	Detector Type	Type of Calibration/QC Test	Frequency	Gas Standard(s)	Acceptance Criteria	Corrective Action
Portable VOC (THC) Analyzer	FID	(1) Multipoint calibration (zero plus three upscale concentrations)	At start of program	Methane or other aliphatic compound	Correlation coefficient ≥ 0.995	Repeat multipoint calibration after checking calibration dilution system
		(2) Zero (span) calibration	Daily	UHP Air or N_2/Methane	Response factor agreement within ± 20 % of mean RF for multipoint calibration	(1) Repeat zero span calibration (2) If still unacceptable, repeat multipoint calibration
		(3) Control sample analysis	Daily, prior to testing	Methane	Measured concentration within ± 10 % of certified concentration	(1) Repeat zero span calibration (2) Repeat control sample analysis
		(4) Drift check	Daily, at conclusion of testing	Methane	Drift value ≤ 20 % of the input value	(1) Flag day's data as questionable (2) Repair or discontinue use of analyzer
	PID	(1) Multipoint calibration (zero plus three upscale concentrations)	At start of program	Benzene or other aromatic compound	Correlation coefficient ≥ 0.995	Repeat multipoint calibration after checking calibration dilution system
	PID	(2) Zero/span calibration	Daily	Benzene or other aromatic compound	Response factor agreement within ± 20 % of mean RF for multipoint calibration	(1) Repeat zero/span calibration (2) If still unacceptable, repeat multipoint calibration
		(3) Control sample analysis	Daily, prior to testing	Benzene or other aromatic compound	Measured concentration within ± 10 % of certified concentration	(1) Repeat zero/span calibration (2) Repeat control sample analysis
		(4) Drift check	Daily, at conclusion of testing	Benzene or other aromatic compound	Drift ≤ 20 % of the input value	(1) Flag day's data as questionable (2) Repair or discontinue use of analyzer
Portable Gas Chromato-graph	FID	(1) Multipoint calibration (zero plus three upscale concentrations)	At start of program	Benzene or toluene	Correlation coefficient ≥ 0.995	Repeat multipoint calibration after checking calibration dilution system
		(2) Zero/span calibration	Daily	UHP air or N_2/methane	Response factor agreement within ± 20 % of mean RF for multipoint calibration	(1) Repeat zero/span calibration (2) If still unacceptable, repeat multipoint calibration
	FID	(3) Control sample analysis	Daily, prior to testing	Benzene	Measured concentration within ± 10 % of certified concentration	(1) Repeat zero/span calibration (2) Repeat control sample analysis
		(4) Drift check	Daily, at conclusion of testing	Benzene	Drift ≤ 20 % of the input value	(1) Flag day's data as questionable (2) Repair or discontinue use of analyzer
		(5) Retention time checks	Daily	Benzene or toluene	None	None
		(6) Analytical blanks	Daily	UHP air or N_2	Measured concentration ≤ 5 % of the instrument span value	Clean/replace system components until acceptable blank can be obtained
		(7) Sampling system blanks	Daily, plus after very high samples	Sample gas	Measured concentration ≤ 5 % of the instrument span value	Clean/replace system components until acceptable blank can be obtained
	FID	(8) Duplicate samples	10 % of sampling points, minimum	Sample gas	None; provides a measure of total sampling variability	None
		(9) Control point samples	After every ten samples or once per day, whichever is greater	Sample gas	None; provides a measure of temporal variability	None
		(10) Background samples	One sample per day	Sample gas	None; provides a measure of background concentration	None
	PID	(1) Multipoint calibration (zero plus three upscale concentrations)	At start of program	Benzene or toluene	Correlation coefficient ≥ 0.995	Repeat multipoint calibration after checking calibration dilution system
		(2) Zero span calibration	Daily	UHP air or N_2/methane	Response factor agreement within ± 20 % of mean RF for multipoint calibration	(1) Repeat zero/span calibration (2) If still unacceptable, repeat multipoint calibration

TABLE 4 *Continued*

Type of Instrument	Detector Type	Type of Calibration/QC Test	Frequency	Gas Standard(s)	Acceptance Criteria	Corrective Action
	PID	(3) Control sample analysis	Daily, prior to testing	Benzene	Measured concentration within ± 10 % of certified concentration	(1) Repeat zero/span calibration (2) Repeat control sample analysis
		(4) Drift check	Daily, at conclusion of testing	Benzene	Drift ≤ 20 % of the input value	(1) Flag day's data as questionable (2) Repair or discontinue use of analyzer
		(5) Retention time checks	Daily	Benzene or toluene	None	None
		(6) Analytical blanks	Daily	UHP air or N_2	Measured concentration ≤ 5 % of the instrument span value	Clean/replace system components until acceptable blank can be obtained
		(7) Sampling system blanks	Daily (plus after very high samples)	Sample gas	Measured concentration ≤ 5 % of the instrument span value	Clean/replace system components until acceptable blank can be obtained
		(8) Duplicate samples	10 % of sampling points, minimum	Sample gas	None; provides a measure of total sampling variability	None
	PID	(9) Control point samples	After every ten samples or once per day, whichever is greater	Sample gas	None; provides a measure of temporal variability	None
		(10) Background samples	One sample per day	Sample gas	None; provides a measure of background concentration	None
Off-site Gas Chromato-graph	FID	(1) Multipoint calibration (zero plus three upscale concentrations)	1 per month	Propane/hexane	Correlation coefficient ≥ 0.995	Repeat linearity check
		(2) Single point calibration check	Daily, prior to sample analyses	Propane/hexane	Response factor agreement within ± 20 % of most recent average RFs for multipoint calibration	Repeat single point calibration
		(3) Retention time check	Daily, prior to sample analyses	Multicomponent standard	Agreement with preestablished relative retention times	Adjust GC conditions and repeat RT check
	FID	(4) Control sample analysis	Daily, prior to sample analyses	Sample gas	(1) Correct identification of 90 % of components (2) For 90 % of components, measured concentrations within ± 30 % of actual concentrations	Repeat control sample analysis
		(5) Duplicate analyses	Minimum 10 % of samples (all duplicate samples will be analyzed in duplicate)	Sample gas	CV ≤ 20 % for ten major sample components	Repeat sample analysis
		(6) Blank analysis	Daily, prior to sample analysis	UHP air or N_2	Total ≤ 20 ppbv-C	(1) Clean system (2) Repeat blank analysis
	PID	(1) Multipoint calibration (zero plus three upscale concentrations)	1 per month	Propane/hexane	Correlation coefficient ≥ 0.995	Repeat linearity check
	PID	(2) Single point calibration check	Daily, prior to sample analyses	Propane/hexane	Response factor agreement within ± 20 % of most recent average RFs for multipoint calibrations	Repeat single point calibration
		(3) Retention time check	Daily, prior to sample analyses	Multicomponent standard	Agreement with preestablished relative retention times	Adjust QC conditions and repeat RT check
		(4) Control sample analysis	Daily, prior to control sample analyses	Sample gas	(1) Correct identification of 90 % of components (2) For 90 % of components, measured concentrations within ± 30 % of actual concentrations	Repeat control sample analysis
		(5) Duplicate analyses	Minimum 10 % of samples. (Duplicate samples analyzed in duplicate)	Sample gas	CV ≤ 20 % for ten major sample components	Repeat sample analysis
	PID	(6) Blank analysis	Daily, prior to sample analysis	UHP air or N_2	Total ≤ 20 ppbv-C	(1) Clean system (2) Repeat blank analysis

TABLE 4 *Continued*

Type of Instrument	Detector Type	Type of Calibration/QC Test	Frequency	Gas Standard(s)	Acceptance Criteria	Corrective Action
	ECD	(1) Quantitative standard	Daily, prior to sample analysis	Multicomponent standard	Response factor agreement within ± 30 % of three day rolling mean RFs for all components	Repeat calibration
		(2) Retention time check	Daily, prior to sample analyses	Multicomponent standard	None; will provide basis for comparison of FID/PID results to ECD results	None
		(3) Control sample analysis	Daily, prior to sample analyses	Sample gas	(1) Correct identification of all components (2) For 90 % of components, measured concentrations within ± 30 % of actual concentrations	Repeat control sample analysis
	ECD	(4) Duplicate analyses	Minimum of 10 % of samples (all duplicate samples analyzed in duplicate)	Sample gas	CV ≤ 20 % for ten major sample components	Repeat sample analysis
		(5) Blank analysis	Daily, prior to sample analyses	UHP air or N_2	Total ≤ 20 ppbv-C	(1) Clean system (2) Repeat blank analysis

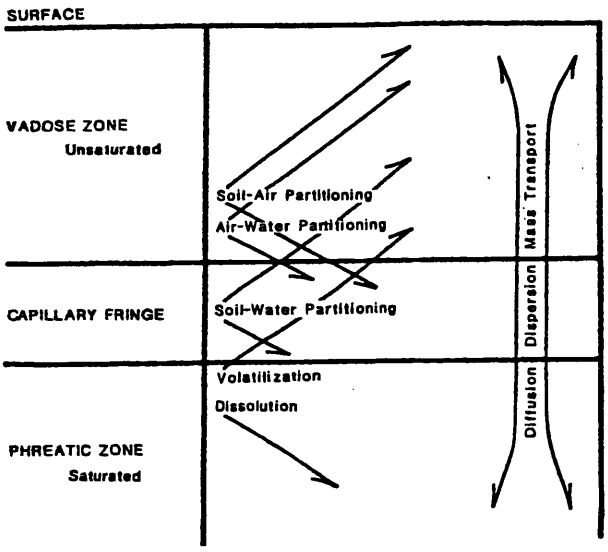
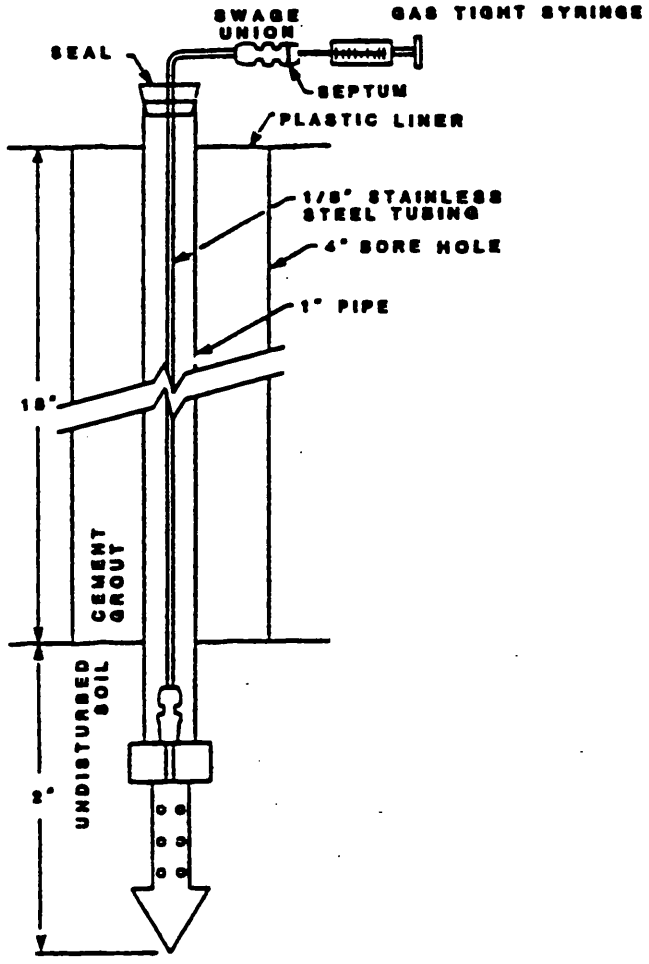
APPENDIX

(Nonmandatory Information)



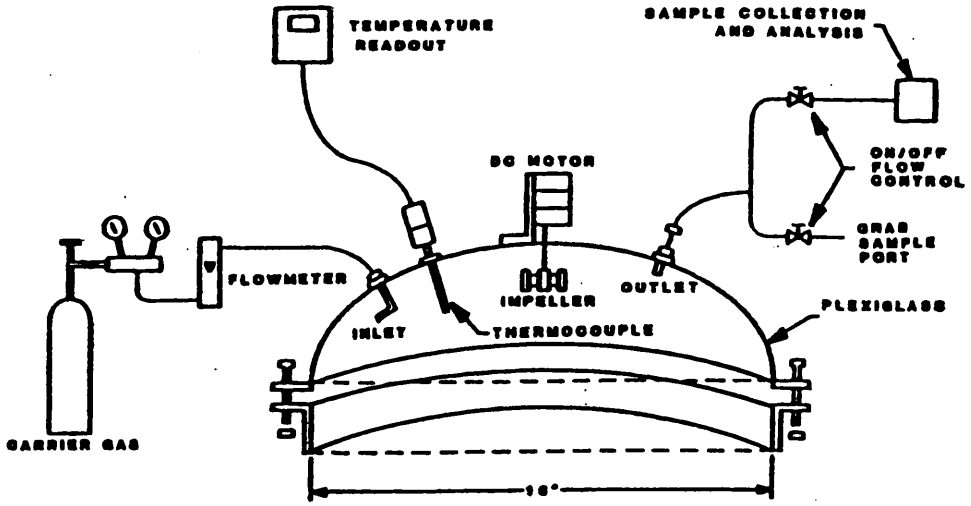
NOTE—The processes indicated by the soil gas monitoring method are partitioning, migration, emplacement and degradation. Partitioning represents a group of processes which control contaminant movement from one physical phase to another, these phases being liquid, free vapor, occluded vapor, solute and sorbed. Migration refers to contaminant movement over distance with any vertical, horizontal or temporal component. Emplacement refers to establishment of contaminant residence in any phase within any residence opportunity. Degradation is the process whereby contaminants are attenuated by oxidation or reduction in the vadose zone, either through biogenic or abiogenic processes. Soil gas monitoring measures the result of the interaction of these processes in a dynamic equilibrium.

FIG. X1.1 Arena of Soil Gas Monitoring



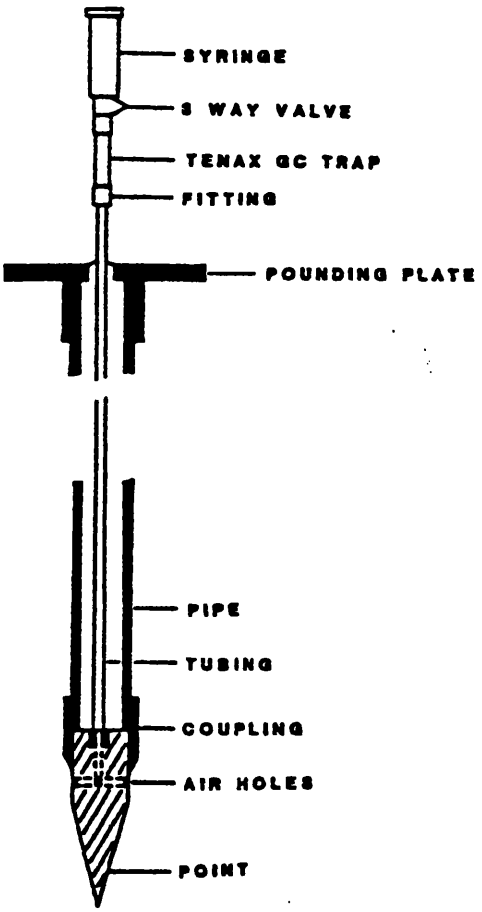
NOTE—Ground probe designed and used by Crow et al., 1985, from Ref (10).

FIG. X1.2 Example of Whole-Air Active Sampling System



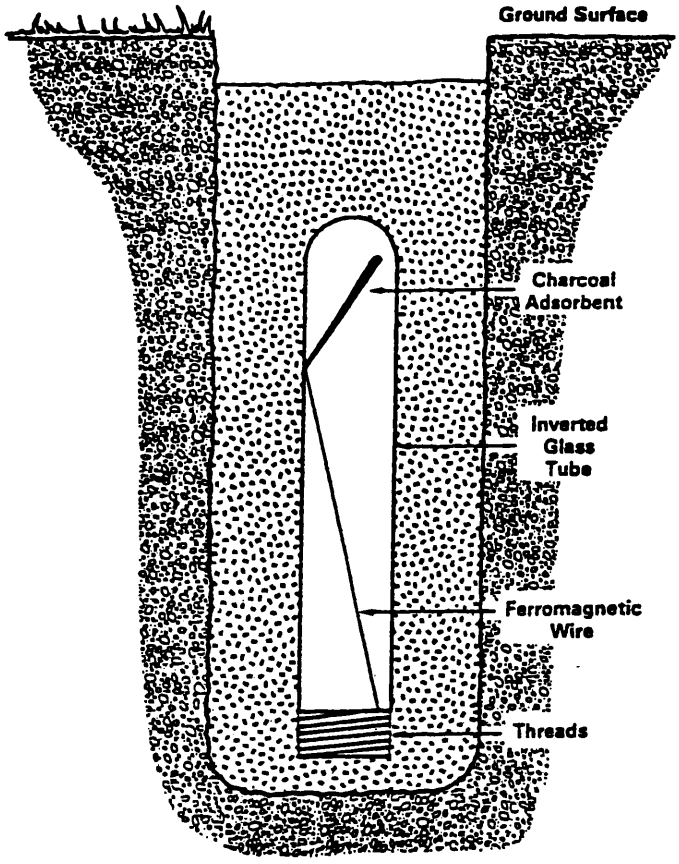
NOTE—Surface flux chamber and penpheral equipment after Eklund et al., 1984, from Ref (10).

FIG. X1.3 Example of Whole-Air Passive Sampling System



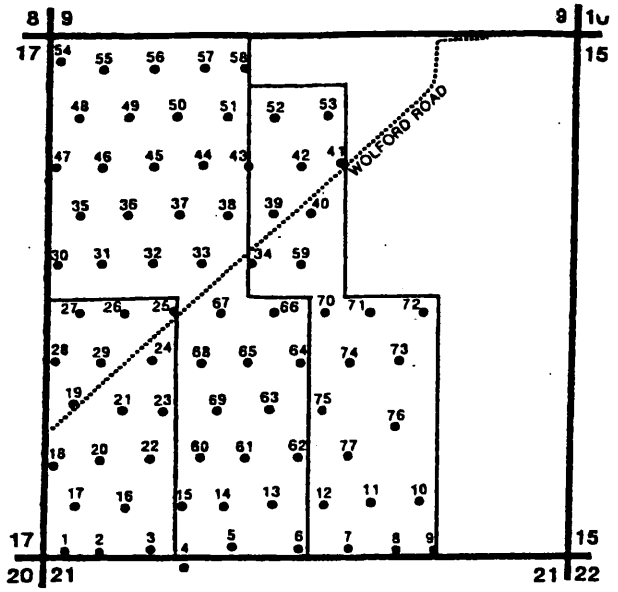
NOTE—Ground probe design used by Swallow and Gachwend, 1983, from Ref (10).

FIG. X1.4 Example of Sorbed Contaminant-Active System



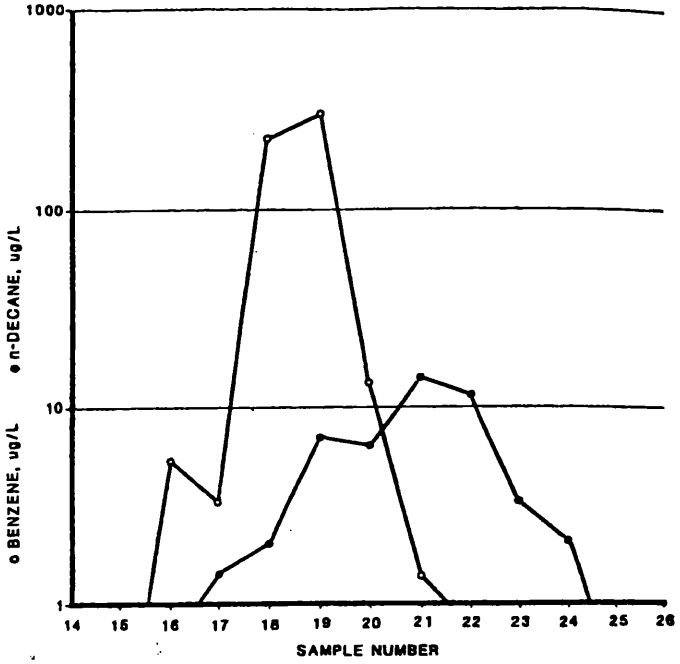
NOTE—Schematic diagram of emplacement of a sorbed contaminant-passive system (10).

FIG. X1.5 Example of Sorbed Contaminant-Passive System



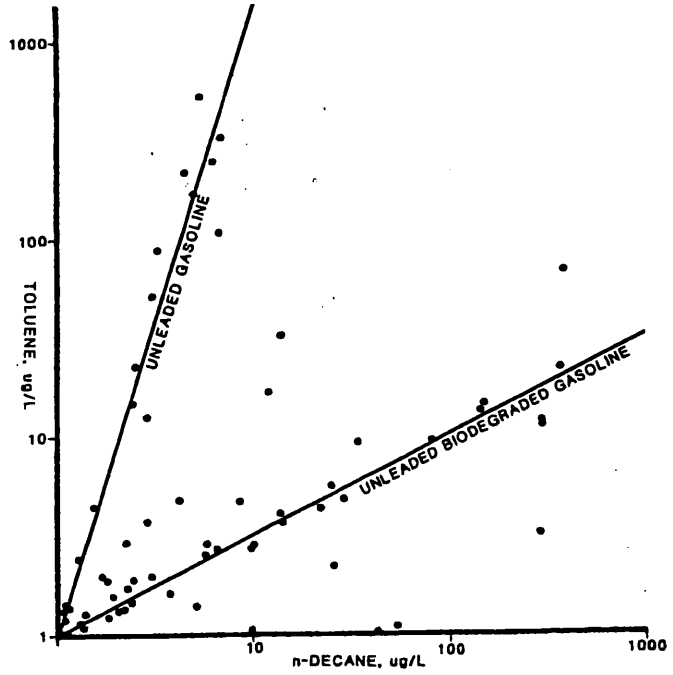
NOTE—In any application, soil gas monitoring can be performed over a wide range of spatial designs, including soil gas sampling in grid patterns at a single depth or multiple depths. This example illustrates a staggered grid pattern of samples recovered at a single depth.

FIG. X1.6 Typical Soil Gas Grid Array and Map Display



NOTE—Soil gas data from survey profiles displayed on an X – Y plot is an effective aid to data interpretation. This display is useful to examine the overall context for soil gas measurement data potentially indicating contamination. If the profile is displayed as a cross section through a grid pattern or as a linear array of sample points, the profile display can illustrate spatially significant groupings of data subpopulations.

FIG. X1.7 Typical Soil Gas Profile



NOTE—Bimodal populations of data that represent coincident contaminant occurrences (for example, soil gas contaminant vapors sourced from converging plumes of two different fuels or mixtures of gasoline and biodegraded gasoline) can be defined using compositional analyses. One technique of compositional analysis is cross-plotting as shown.

FIG. X1.8 Soil Gas Compositional Analysis by Cross Plot

Project # _____ Sample # _____
Sampled by: _____
Date Sampled: _____, 199_____ Time: _____ (AM/PM)
Sampling System (check one):
( ) Whole air-active approach
( ) Whole air-passive approach
( ) Sorbed contaminants-active approach
( ) Sorbed contaminants-passive approach
( ) Headspace or extraction approach
( ) Soil pore liquid headspace approach
Sample Type (check one):
( ) Direct field sample
( ) Field blank
( ) Travel blank
( ) Sample container blank
( ) Sample probe blank
( ) Sample replicate
Spiked? _____ with _____ cc of _____
Potential reaction products due to spiking: _____
System purge volume: _____ Volumes purged: _____ Sample volume: _____
Sorbent Device: Installed _____ (AM/PM), _____, 199_____
Recovered _____ (AM/PM), _____, 199_____
Sample container type: _____ Sample container #_____
Integral analyzer: _____ Detector: _____
Analyzer response: _____ (units) _____
Surface conditions (pavement, wet, frost, etc.) _____
Sample depth: _____ Sampling rate: _____
Sample horizon data-visual estimates:
Vadose zone make-up: ( ) Native soil+rock ( ) Fill ( ) Rock
Soil composition: Clay, _____%
Soil organic matter, _____%
Fine granular material, _____%
Coarse granular material, _____%
100 %
Moisture content of sampling horizon (qualitative):

	( ) Dry
( ) Very	( ) Damp
( ) Slightly	( ) Moist
	( ) Wet

Other characteristics of the sampling horizon:

( ) Free water present	( ) Probable connection to surface macropores
( ) Free product present	
( ) Contaminant odors	( ) Indurated
( ) Poor perm. to vapor	( ) Soil discoloration
( ) Near slope or vent	( ) _____

_____
Investigator Signature/Date

_____
Investigator Affiliation

Designation: D 5321 – 92

Standard Test Method for Determining the Coefficient of Soil and Geosynthetic or Geosynthetic and Geosynthetic Friction by the Direct Shear Method[1]

This standard is issued under the fixed designation D 5321; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers a procedure for determining the shear resistance of a geosynthetic against soil, another geosynthetic, or a soil and geosynthetic in any combination.

1.1.1 The test method is intended to indicate the performance of the selected specimen by attempting to model certain field conditions.

1.2 The test method is applicable for all geosynthetics. Remolded or undisturbed soil samples can be used in the test device.

1.3 The test method is not suited for the development of exact stress-strain relationships within the test specimen due to the non-uniform distribution of shearing forces and displacement.

1.4 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.5 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions*—For definitions of terms relating to soil and rock, refer to Terminology D 653. For definitions of terms relating to geosynthetics, refer to Terminology D 4439.

3.2 *Descriptions of Terms Specific to This Standard:*

3.2.1 *adhesion, c_a (FL^{-2}), n*—the shearing resistance between soil and another material under zero externally applied pressure. **(D 653, D-18)**

3.2.2 *angle of friction, n*—(angle of friction between solid bodies) (degrees) the angle whose tangent is the ratio between the maximum value of the shear stress that resists slippage between two solid bodies at rest with respect to each other and the normal stress across the contact surface. **(D 653, D-18)**

3.2.3 *atmosphere for testing geosynthetics, n*—air maintained at a relative humidity of 65 ± 5 % and temperature of 21 ± 2°C (70 ± 4°F). **(D 4439)**

3.2.4 *coefficient of friction, n*—a constant proportionality factor, relating normal stress and the corresponding critical shear stress, at which sliding starts between two surfaces. **(D 653, D-18)**

3.2.5 *direct shear friction test, n*—for geosynthetics, a procedure in which the interface between a geosynthetic and any other surface, under a range of normal stresses specified by the user, is stressed to failure by the horizontal movement of one surface against the other.

3.2.6 *geosynthetic, n*—a planar synthetic product manufactured from polymeric material used with soil, rock, earth, or other geotechnical engineering-related material as an integral part of a man-made project, structure, or system. **(D 4439)**

4. Summary of Test Method

4.1 The coefficient of friction between a geosynthetic and soil, or between any geosynthetic combination selected by the user, is determined by placing the geosynthetic and one or more contact surfaces, such as soil, within a direct shear box. A constant normal compressive stress is applied to the specimen, and a tangential (shear) force is applied to the apparatus so that one section of the box moves in relation to the other section. The shear force is recorded as a function of the horizontal displacement of the moving section of the shear box. The test is performed for a minimum of three different normal stresses, selected by the user, to model appropriate field conditions. The peak (or alternatively, the residual) shear stresses recorded are plotted against the applied normal compressive stresses used for testing. The test data are generally represented by a best fit straight line whose slope is the coefficient of friction between the two materials where the shearing occurred. The y-intercept of the straight line is the adhesion.

SOIL GAS SURVEY

Soil gas surveys are a field screening method typically used to determine the presence of volatile organic compounds in unsaturated, subsurface soils. The surveys provide real time data in a rapid and non-disruptive manner at less than half the cost of traditional soil sampling.

Soil gas sampling identifies the nature and concentration of compounds found in the pore space of soils through the use of field monitoring equipment. Volatile compounds present in the soil volatilize from the soil and water matrices into the interstitial pore spaces of the soil These volatilized gases are detected by soil gas sampling. The amount of VOCs in the soil gas phase is primarily dependent upon the partitioning coefficient between the aqueous phase and the vapor phase (Henry's Law constant), the soil phase and the vapor phase, soil type, concentration of contamination and sampling distance from the source of the concentration.

The objective of a soil gas survey is to delineate horizontal and vertical extent of VOC contamination in subsurface soils and help predict the future horizontal and vertical movement of VOC compounds. Data collected also provides necessary information regarding potential soil remediation.

SAMPLING PROCEDURE

Typically a grid is developed covering the investigation area. Site maps indicating potential underground areas of interest (such as buried tanks and pipes) are helpful in identifying sample locations. Soil gas samples are collected by driving 5 foot long, 5/8 inch diameter, hollow stainless steel soil gas sampling probes equipped with retractable sample points. Soil gas samples are collected through the retractable point at the desired depth.

Typically, and depending on soil types, a pilot hole will be drilled into the top 2 feet of soil to facilitate installation of soil gas sampling probes. Soil gas probes are placed into the pilot hole and, utilizing probe extensions, driven to the desired sampling depth. Compacted soils limit the attainable sample depth at 3-5 feet while less compact soils may be sampled at depths approaching 12-15 feet. The probes are driven into the soil utilizing a 30 pound electric hammer drill equipped with a custom made drive head that protects the probe from damage while driving.

After reaching the desired sampling depth, probes are extracted approximately 4 inches with a high lift utility jack in order to sufficiently open the retractable sampling point. The retractable sample points consist of a 4 inch length of 1/2 inch machined stainless steel pipe with several 1/16 inch holes drilled through the horizontal plane. A stainless steel mesh covers the length of 4 inch pipe to prevent soil particles from entering the pipe during sampling.

Sample depth measurements are recorded and a sampling port attached to the top of the soil gas probe. A static measurement of the soil gas, utilizing an Organic Vapor Monitor (OVM), present in the probe is conducted at this time. A portable electric vacuum pump is attached to the probe via the sample port and approximately 100-200 probe volumes (2.7-5.5 cubic feet) of soil gas is purged through the probe before a soil gas sample is obtained. The discharge from the vacuum pump is monitored using an OVM. The dynamic purging of the soil gas probe produces a cone of influence encompassing soil void areas some distance, depending on soil type, from the actual point of probe location, allowing for the determination of VOCs in an extended subsurface area. Beginning, maximum and ending applied vacuum and OVM readings are recorded.

When purging is completed, soil gas samples are collected from the sample port using 1 ml syringes for immediate injection and analysis on a portable Photovac gas chromatograph and the probe is removed from the ground utilizing the utility jack. The Photovac is equipped with a photoionization detector (PID) and is capable of detecting VOCs in air at concentrations as low as 50 ppbv. It is very mobile and may be set up and operated in the field.

Results from the soil gas sampling are used to develop VOC contours illustrating areas of varying VOC concentrations to determine the extent of VOC contamination in the subsurface soils and help in the placement of soil borings and groundwater monitoring wells to further identify the extent of subsurface contamination.

Section 1
Introduction

1.1 General

This study involves evaluating the feasibility of constructing cargo buildings, concrete aprons, and a taxiway extending from Runway 34-16 as part of development of the T.F. Green Airport in Warwick, Rhode Island. The cargo building locations will be over an existing landfill located south of the existing runway. **Figure 1-1** shows the location of the site and the surrounding area. A limited environmental site investigation report was submitted to Rhode Island Airport Corporation (RIAC) under separate cover.

1.2 Proposed Site Improvements

For purposes of this study, the proposed site improvements are assumed to consist of the following:

- Four cargo facility buildings, each approximately 100 feet by 300 feet in plan dimensions. The cargo buildings are proposed to be suitable for medium to heavy warehouse loading, which is assumed to be equivalent to approximately 500 pounds per square foot (psf) average building loading;

- Concrete taxiway and aprons are proposed between the existing runway and the proposed buildings. Up to three 757 airplanes are proposed to be parked at each building. The average loading on the taxiway and/or aprons is assumed to be equivalent to approximately 500 psf.

- Regrading and the placement of a landfill cover is proposed. The center of the landfill is proposed to be cut between 3 feet and 20 feet to reach the desired grade. Perimeter areas of the landfill are proposed to be filled between 6 and 14 feet to reach the desired grade.

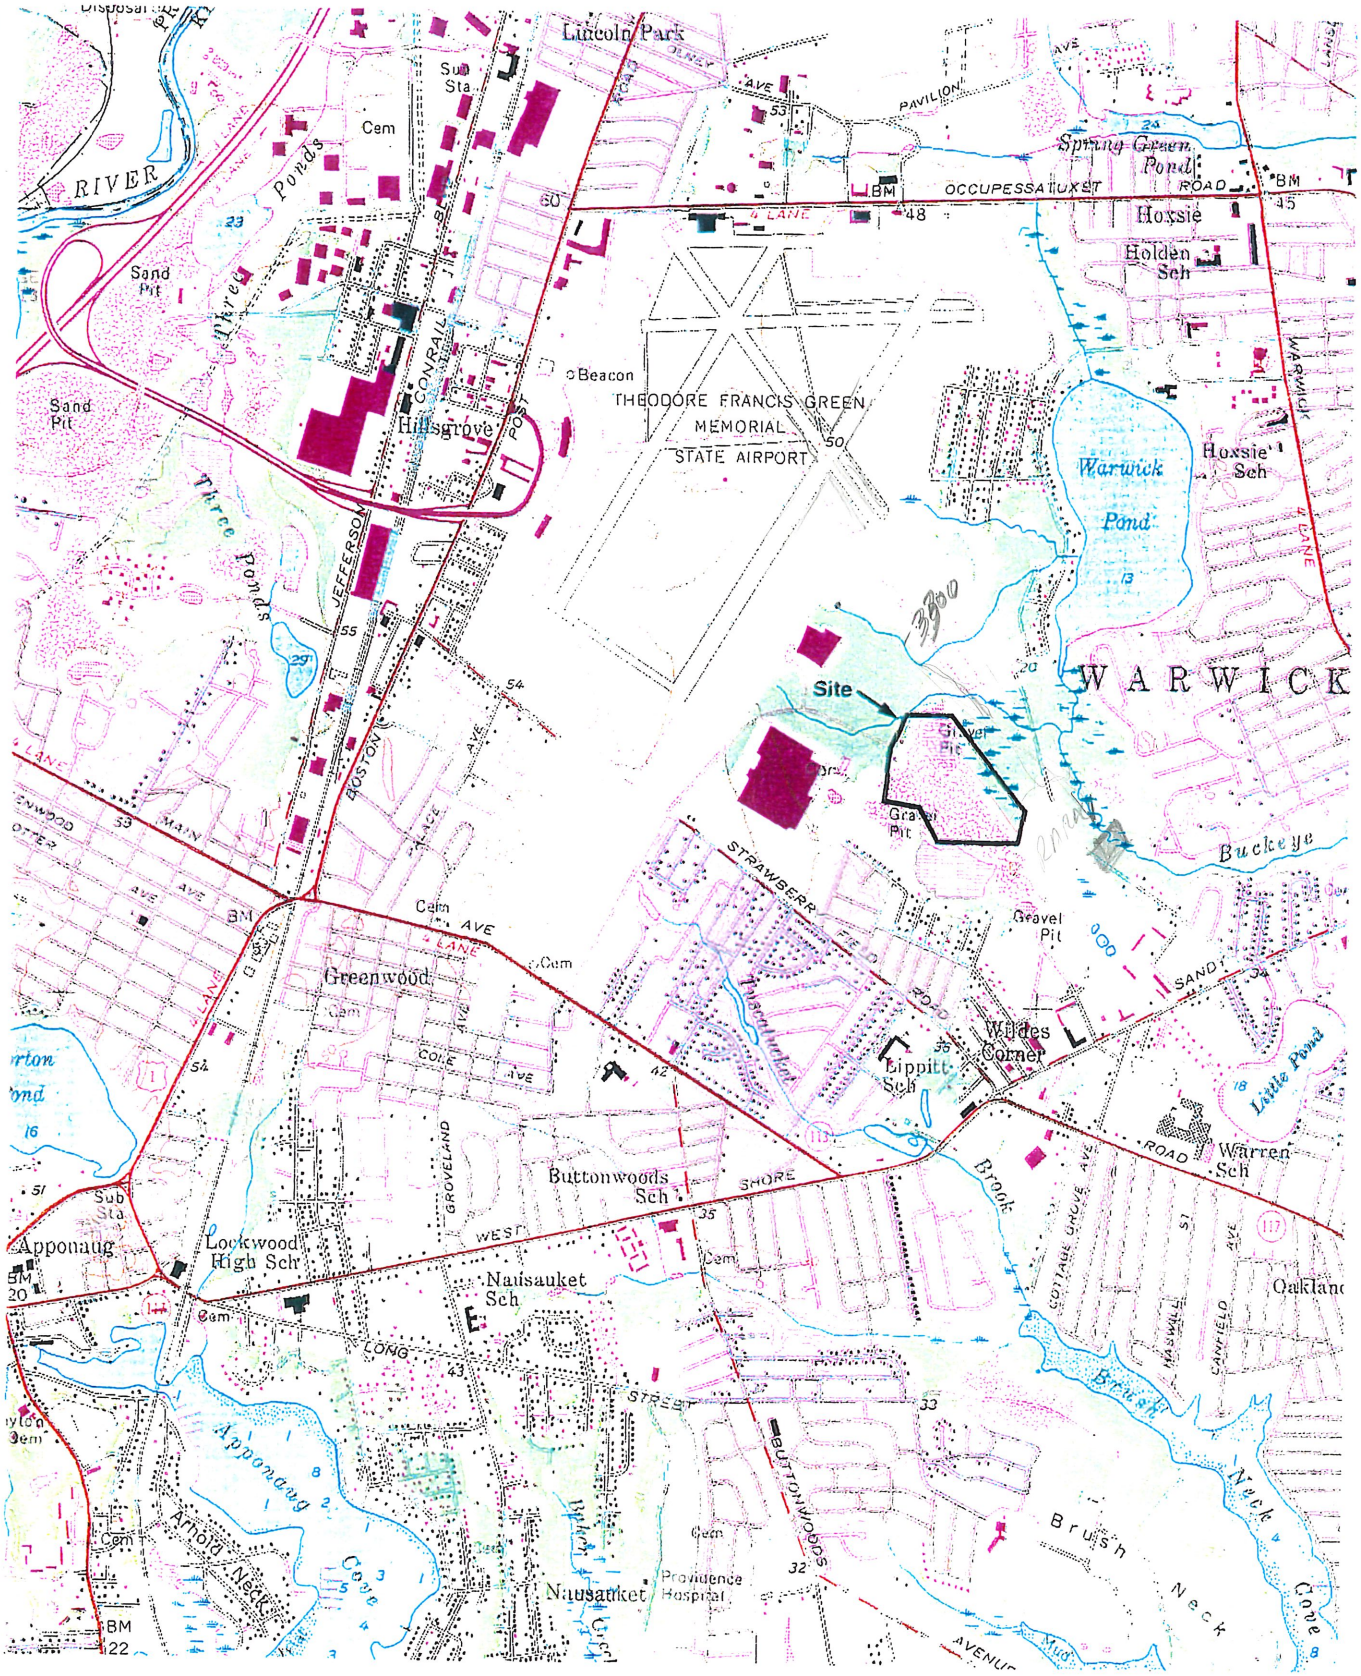
Final site improvements may vary from those presented herein.

1.3 Elevation Datum

Elevations noted herein are referenced to the National Geodetic Vertical Datum (NGVD) 1929.

1.4 Purpose and Scope

The purpose of this study was to investigate subsurface conditions at the location of the proposed airport expansion and to provide geotechnical engineering recommendations to assess the feasibility of constructing the proposed buildings and site improvements. Specifically, the scope of the work included the following:



Base Map: USGS Quad - East
Greenwich, RI - 1975
Scale 1" = 2083'

CDM Camp Dresser & McKee Inc

Figure 1-1
Site Locus

- excavating test pits at 23 locations around the perimeter of the landfill to delineate the extent of landfill waste;
- advancing eight (8) test borings within the limits of the landfill to investigate subsurface conditions and obtain soil samples for physical laboratory testing;
- installing monitoring wells in six (6) of the completed test borings;
- conducting laboratory tests to assist with classification and estimating engineering properties of the soil encountered;
- analyzing foundation system alternatives and ground improvement techniques that might be required;
- providing a conceptual-level cost comparison for the foundation system alternatives and/or ground improvement techniques analyzed;
- making recommendations for additional investigations and engineering evaluations for final design of the proposed facilities; and
- preparing this engineering report which presents CDM's recommendations, including data collected as part of the investigation.

1.5 Report Limitations

The recommendations contained in this report have been prepared for the proposed cargo facilities at the T.F. Green Airport in Warwick, Rhode Island as understood at this time and described in this report. This report has been prepared in accordance with generally accepted engineering practices. No other warranty, express or implied, is made. In the event that changes in the design or location of the site improvements occur, the conclusions and recommendations contained herein should not be considered valid unless verified in writing by CDM.

Section 2
Site and Subsurface Conditions

2.1 Existing Conditions

The site is the former Truk-Away Landfill. The landfill covers approximately 34 acres. The landfill area is bounded to the west by industrial property, to the north by Runway 34-16, to the east by wetlands at the end of the runway and a former City of Warwick dump, and to the south by residential property.

The landfill surface is vegetated with low growing shrubs and grasses and occasional stands of small trees. Ground surface at the central part of the landfill is relatively flat and at about El. 42. The perimeter of the landfill is approximately 10 to 30 feet lower than the center. Side slopes from the center to the perimeter of the landfill are gradual (generally 4H:1V or flatter).

Correspondence that were made available to CDM from Truk-Away and Sanitas Waste Disposal to the Division of Solid Waste Management during the 1970's suggests that the site is underlain by extensive peat deposits. The waste materials placed in the landfill are not well documented but reference is made to "rubbish and construction demolition debris." There is no mention of hazardous material disposal in the information made available to CDM.

2.2 Subsurface Investigations

2.2.1 Test Pits

To evaluate the limits of waste at the landfill, TMC Services, Inc. of Bellingham, Massachusetts excavated test pits at 23 perimeter locations between October 18 and 19, 2000. A CAT 426B backhoe and a CAT 315B excavator were used to make the excavations. At several test pit locations, multiple test pits were excavated for the purpose of evaluating the approximate extent of the waste. Up to four test pits were excavated at these locations. A total of 38 test pits were excavated.

Table 2-1 presents a summary of the conditions encountered in the test pits. The approximate locations of the test pits are shown on **Figure 2-1**. The locations of the test pits shown on the plan indicate the limit of waste found within the boundaries of the site. At several locations however, the waste extended beyond the limits of the site boundaries, particularly in the southern and western portions of the site.

Test pit depths varied from 0.5 feet to 12 feet below ground surface. A CDM representative observed the test pit excavations in the field. Test pit locations were field surveyed after completion. Upon completion, the test pits were backfilled with the excavated material. Waste material observed in the test pits included plastic, paper, glass, wood, rubber, clothing and brick material.

2.2.2 Test Borings

Eight test borings (MW-1, SB-2, MW-3, SB-4, MW-5, MW-6, MW-7, MW-8) were drilled within the limits of the site to investigate the subsurface conditions. The test borings were drilled by New Hampshire Boring Inc. of Derry, New Hampshire between November 6 and 22, 2000. The test borings were drilled using an all-terrain vehicle (ATV) drill rig. All test borings fully penetrated the existing landfill waste material and were terminated approximately 30 feet into the naturally deposited, inorganic sand and gravel stratum underlying the site. Test boring depths ranged from 32 feet to 77 feet below the existing ground surface.

Split-spoon sampling was conducted at five-foot intervals at each boring location in accordance with ASTM D1586 (2-inch-diameter sampler driven 24 inches by blows from a 140-pound hammer falling freely for a 30-inch drop). The number of blows required to drive the sampler each 6-inch increment was recorded and the Standard Penetration Resistance (N-value) was determined as the sum of the blows over the middle 12 inches of penetration. Representative soil samples were taken from each split-spoon collected in the naturally deposited soils and stored in jars for later review and laboratory testing. Samples of the waste material were collected in the field for classification only. No samples of the waste were collected for later review and geotechnical laboratory testing.

Test borings, where monitoring wells were not installed, were backfilled with bentonite grout to an elevation approximately 5 feet above the bottom of the waste material. The remainder of the test borings were backfilled with waste and spoil material. Material not used to backfill the hole was drummed for later disposal by others.

A CDM representative observed the test borings in the field and test borings were located by field survey. Elevations were estimated relative to available site topography. Logs of the test borings, prepared by the driller and reviewed by CDM, are included in Appendix A. Figure 2-1 shows the approximate locations of the explorations.

2.3 Monitoring Well Installation

Six monitoring wells were installed in completed boreholes (MW-1, MW-3, MW-5, MW-6, MW-7, MW-8) as part of the subsurface investigation. The monitoring wells were installed at depths ranging from 13 feet to 34 feet below existing ground surface. Well construction consisted of installing a 10-foot screen with the bottom of the screen located approximately 7 feet below the measured groundwater level.

The monitoring wells were backfilled with bentonite to the bottom of the screen. The annulus around the well screen was backfilled with sandpack to a level approximately three feet above the top of the screen interval. Sandpack was allowed to settle while slowly removing downhole tools. The remaining length of borehole was backfilled around the well riser pipe with bentonite. The monitoring well screen used was

constructed of 2-inch-diameter PVC with 0.020-inch machine-slots. The monitoring well riser pipe used was constructed of 2-inch-diamter threaded PVC. A road box was installed at each well location and extends approximately 2.5 feet above ground surface.

2.4 Subsurface Conditions

2.4.1Subsurface Soil Conditions

Subsurface soil conditions were interpreted from the test borings conducted at the site and our understanding of the landfill history and local geology. The test pits were not used to interpret the subsurface conditions but were used only to estimate the extent of the waste at the site. Test borings drilled within the landfill typically encountered cover soil and waste overlying naturally deposited peat, sand and gravel.

Landfill cover material, consisting of loose to medium dense, tan, fine to coarse SAND with varying amounts of gravel and silt, was encountered in all of the borings taken within the limits of the landfill. Cover material was not encountered in perimeter test borings SB-4 and MW-7. Cover thickness ranged from 1 to 5 feet with SPT N-values ranging from 4 to 29 blows per foot (bl/ft).

Waste was encountered in all of the test borings at the site except test boring MW-7. Waste material typically consisted of loose to very dense black wood, paper, glass, cloth, metal, wire and plastic. Waste thickness ranged from 15 to 33 feet with N-values ranging from 4 bl/ft to 100 blows for 3 inches.

In test borings MW-3, SB-4, MW-5, and MW-6 the lower portion of the waste was mixed with the underlying peat soils for 5 to 30 feet in thickness. Samples taken within this zone consisted of dark brown fibrous PEAT with varying amounts of waste material, silt, and sand. Typical N-values in the peat and waste mix ranged from weight of rod (WOR) to 21 bl/ft. In test borings MW-5 and MW-6, the lower portion of the waste was mixed with sand for approximately 5 to 8 feet. Samples taken within this zone consisted of loose to medium dense, sand, trace metal. Typical N values in the waste and sand mix ranged from weight of rod (WOR) to 10 bl/ft.

In test boring MW-3, an additional 3 feet of PEAT that did not contain waste was encountered. Peat soils were not encountered in test borings MW-1, SB-2, and MW-7. These test borings are located within the footprint of Building No. 1 and Building No. 2 in the northern and western sections of the landfill, which are farthest from the wetlands.

The natural inorganic soils encountered below the waste and peat deposit, in all of the test borings, typically consisted of loose to dense, gray, fine to coarse SAND and GRAVEL, with varying amounts of silt. SPT N-values for this layer varied between 3 and 35 bl/ft. All test borings were terminated at least 30 feet into this layer.

Table 2-2 presents a summary of subsurface explorations. **Figure 2-2** shows a geologic cross section of the subsurface conditions encountered in the test borings at the site.

2.4.2Groundwater Levels

Groundwater levels in each test boring were estimated based on the conditions of the samples obtained and by the observed water levels within the borehole at the time of drilling. Observed groundwater level ranged from 2.5 ft. to 27 ft. below existing ground surface, which corresponds to approximately El. 16.8 to El. 11.0. Monitoring wells installed at the site were developed and water levels were recorded following the subsurface investigation. Water levels recorded in the monitoring wells on December 13, 2000 ranged from 4.7 to 22 feet below ground surface, which corresponds to approximately El. 24.2 to El. 15.9.

Table 2-2 presents groundwater levels measured in the boreholes at the time of drilling and recorded in the monitoring wells on December 13, 2000. In the areas of proposed building construction, depth to groundwater was observed at approximately 22 feet below ground surface.

Water levels measured in the explorations should not necessarily be considered to represent stabilized groundwater levels. In addition, water levels are expected to fluctuate with season, temperature, climate, construction in the area, and other factors. Actual conditions during construction may be different from those observed at the time of the explorations.

2.4.3Variation in Subsurface Conditions

Interpretation of general subsurface conditions presented herein is based on waste, soil, and groundwater conditions observed at the test boring locations. However, subsurface conditions may vary between exploration locations. If conditions are found to be different than assumed, recommendations contained in this report should be reevaluated by CDM and confirmed in writing.

2.5 Laboratory Testing

Laboratory grain size analyses were performed on selected split spoon samples obtained from the test borings. Gradation analyses were performed in accordance with ASTM D422 on seven representative samples of the sand and gravel deposit collected from test borings MW-1, SB-2, SB-4, MW-5, MW-6, MW-7, MW-8. The purpose of the testing was to assist with soil classification.

Laboratory tests were performed on selected peat samples collected at the site to determine organic content, water content, and plasticity. Atterberg limit (ASTM D4318) and organic content (ASTM D2974) tests were performed on peat samples recovered from test boring MW-3 and SB-4. The results of the laboratory tests are included in Appendix B.

2.6 Geotechnical Characteristics of the Peat Deposit

Peat is typically a fibrous aggregate of decayed and decaying vegetation matter and soil. Peat deposits are characterized as having high organic content, high void ratios and water contents, and, usually, high compressibility and low strength. However, the properties of peat can vary substantially depending on age, deposition, water content, and previous loading as well as many other factors.

The following are the laboratory test results on peat samples collected at the site and a comparison to typical ranges for organic soils:

Parameter	Range for Peat Soils at T.F. Green Airport Landfill	Typical Range for Organic Soils [1]
Organic Content (% by weight) – 61.1%	13.1 – 61.1%	5 – 100%
Water Content (% by weight)	327.6 – 797.9%	30 – 1200%
Liquid Limit (LL)	254 – 645	30 – 900%
Plasticity Index (PI)	76 – 204	Non-plastic - 500

[1] Reference: Naval Facilities Engineering Command, Design Manual 7.01 Soil Mechanics

At this time, limited information is available on the peat deposits at the site. However, based on the test results, the peat deposits at the site appear to have relatively high organic content and water content, and should be expected to experience significant consolidation and settlement when loaded. In addition, the high organic content of the peat should be expected to result in long-term creep settlement of structures placed over the peat as the organic matter decays over time.

The peat deposits located below the landfill and around the immediate perimeter of the landfill, as mentioned previously, are typically mixed with landfill waste material. Mixing of the waste with the peat has likely had an effect on the properties of the peat. In addition, the peat located below the limits of the landfill is likely to have already undergone some compression due to the weight of the overlying waste. However, there are areas beyond the perimeter of the landfill where the proposed taxiways are to be constructed where thick peat deposits are expected. These deposits are expected to be highly compressible. Additional subsurface investigations of the peat should be conducted prior to final design.

2.7 Geotechnical Characteristics of the Waste Material

The geotechnical characteristics of municipal solid waste material depends greatly on several factors including: composition of the waste material, method of placement, organic content, moisture content, and age. In addition, characteristics of waste material typically vary within broad ranges, can change significantly with time, and are not easily measured using standard field investigation and sampling techniques. Regardless of the difficulty in assessing accurate waste characteristics, some general trends have been observed for municipal solid waste (MSW) material.

- MSW is typically lighter than mineral soil deposits. Unit weight of MSW typically ranges between 40 to 90 pounds per cubic foot (pcf).

- MSW is typically compressible, however, the degree of compressibility can vary greatly. Compression occurs both immediately upon loading, which is often the result of distortion, bending, crushing, and reorientation of the materials, and for a long period of time after loading, which is often the result of biological decomposition of the organic component of the waste, corrosion, oxidation, and combustion processes. Based on the information obtained as part of this study, the compressibility of the waste cannot be accurately estimated. However, for purposes of this study, we have assumed that the waste at the site is moderately compressible.

- The strength of MSW varies greatly but is typically primarily frictional in nature with some apparent cohesion. Observed strength is often dependent on the degree of interlocking or overlapping of the waste material. SPT N-values recorded in the waste at the site indicate that it is loose to medium dense and thus, for purposes of this study, is expected to provide low to moderate strength characteristics.

At this time, only very limited information on the geotechnical characteristics of the waste at the site is available. However, based on the existing information made available to us about the landfill construction and composition and the waste material observed in the test borings, the waste at the site should be expected to be moderately compressive under immediate loading with the potential for long-term creep settlement of structures placed over the waste. Additional subsurface investigations of the waste material should be conducted prior to final design.

Section 3
Geotechnical Engineering Evaluation and Preliminary Design Recommendations

3.1 General

This section describes our geotechnical engineering evaluation of the project site and our preliminary design recommendations for foundation support of the proposed site improvements including the taxiways, aprons, and cargo buildings. These recommendations should be used only to assess the feasibility of constructing the proposed facilities at the site and not for final design.

3.2 Foundation Support

The existing waste and peat soils are not considered suitable for foundation support of the proposed taxiways, aprons, or structures. These strata are highly compressible and lack sufficient strength to adequately support the proposed site improvements without excessive post-construction settlement. Total post-construction settlement in these strata is estimated to be in the order of 2 feet to 6 feet as a result of the added load from the proposed site improvements. This estimate of total settlement includes both primary and long-term settlement. Primary settlement is a combination of immediate and consolidation settlement that typically occurs relatively quickly after a load is added in these types of materials, i.e., waste and peat. Long-term settlement, or creep settlement, occurs for many years after primary settlement is complete and under a constant load.

Several options are available to reduce post-construction settlement. The waste and peat could be removed from within the limits of the proposed site improvements and replaced with granular fill. However, due to the expected large volume of waste and peat and high cost, this option is not recommended.

Ground improvement techniques may be used to improve the performance of the underlying materials and reduce settlement. Alternatively, the structures can be supported on deep foundations that extend through the waste and peat and into the underlying sand and gravel stratum.

3.2.1 Ground Improvement

Ground improvement techniques have been used in the U.S. for many years as a means to increase density, improve strength, reduce compressibility and/or permeability, increase bearing capacity, and reduce post-construction settlement of problematic soil deposits. Two methods of ground improvement that are considered applicable to improving the waste and/or peat soils at the site include soil preloading and deep dynamic compaction. The following is a brief description of each method, it's application to the project, and a discussion of relative costs.

3.2.1.1 Soil Preloading

Soil preloading consists of temporarily placing excess fill in the area of future construction and over a compressible layer so as to cause consolidation settlement to occur prior to construction rather than after construction. Once the layer has consolidated sufficiently, the excess fill is removed. The amount of excess fill required and duration of a preloading program are dependent on the type and thickness of material that is being preloaded as well as the foundation loading and tolerable settlement of the proposed permanent structures. Soil preloading is considered appropriate for portions of the site that are primarily underlain by peat soil rather than primarily waste material. The southern and eastern portion of the site appears to be primarily underlain by peat deposits of varying thicknesses.

We estimate that a preload program should consist of at least 10 feet of excess fill placed over the area of the proposed site improvements for approximately 6 to 36 months. After removal of the excess fill, the proposed site improvements are estimated to experience up to 6-in. of post-construction primary (consolidation) settlement due to the long term consolidation of the peat soils.

Although a preload program will help limit post-construction consolidation settlement, long-term creep settlement will not be mitigated. Organic soils with a high organic content, such as peat, should be expected to experience significant long-term creep settlement. The amount of long-term settlement is dependent on the thickness and creep characteristics of the underlying material as well as time. Based on the limited information available as part of this study, we estimate that the long-term creep settlement of the peat soils at the site will be about 1 foot to 2 feet over approximately 30 years.

The cost of a preload program is estimated to be approximately $15/cy of excess material placed and removed plus approximately $10,000 for installation and monitoring of settlement points which are used to observe and evaluate the performance of the preload program. Therefore, a preload program at the site is estimated to cost about $250,000 per acre plus survey costs. The proposed cargo buildings, aprons, and taxiways will comprise an estimated 20 acres, of which approximately 10 acres is primarily underlain by peat deposits and would be consolidated using preloading. Therefore, this option could cost roughly 2.5 million dollars. The cost of a preload program could be reduced by reducing the amount of excess fill placed, however, the duration of the program would need to be lengthened to allow for consolidation to occur.

It should be noted that our evaluation of a preload program is based on limited subsurface information. Additional subsurface investigations and laboratory testing to determine the consolidation characteristics of the in-situ materials is required prior to final design of a preload program.

3.2.1.2 Deep Dynamic Compaction

Deep dynamic compaction (DDC) is a ground improvement technique that consists of repeated tamping of the ground surface by dropping heavy steel or concrete weights. Typically the weights are about 6 to 20 tons and are dropped in a grid pattern by a crane from various heights depending on the amount of energy required. Dropping the weights produces shock waves that propagate through the underlying material that consolidates the material resulting in reduced void space, increased density and reduced long-term settlement of the underlying material. Larger weights and/or higher drop heights are required to treat thick deposits.

DDC is most effective on material that is above the water table and primarily granular in nature. The presence of groundwater and high fines content of the material tend to dampen the impact of DDC. DDC is not considered suitable for treatment of peat soils.

Once compacted, volume change of the underlying material of about 5 to 10 percent can be achieved for older landfills and up to about 25 percent for younger landfills. The increase in volume change for younger landfills, i.e., landfills which are still actively undergoing degradation, is thought to represent that portion of settlement that occurred previously in the older, now less active, landfills. The amount of volume change resulting from DDC is estimated by measuring how much the ground surface is lowered, i.e., crater depth. If insufficient volume change is initially achieved, repeated drops at one location may be required.

Light-weight structures constructed on top of DDC waste at other landfill sites have been reported to have experienced post construction settlement in the range of 0.25 percent of the underlying consolidated waste thickness (Ref. Lukas and Seiler, 1994). For purposes of this study, we estimate that the medium-weight to heavy-weight cargo facilities proposed at the site may experience up to approximately 12-in. of post construction primary settlement after DDC treatment. However, settlement estimates of DDC-treated waste should be made based on the characteristics of the site specific waste. Thus, a geotechnical subsurface investigation program is required after the DDC program is completed.

It should be noted that DDC-treated waste is still expected to experience some long-term creep settlement. The amount of creep settlement is dependent on the age of the waste and the amount of degradation that has occurred previously. For purposes of this study, we estimate that up to 1 foot to 2 feet of post construction long-term creep settlement may occur at the site after DDC treatment.

We estimate that DDC will cost about $1.50 to $2.00 per square foot (sf) of treated area or about $65,000 to $87,000 per treated acre. The proposed cargo buildings ramp area and taxiway will comprise an estimated 20 acres, of which approximately 10 acres is primarily underlain by waste and could be consolidated using DDC. Therefore, this option would cost roughly $650,000 to $870,000. This estimate does not include the cost of importing fill soils to the site to make up the volume loss, i.e., surface settlement, associated with DDC.

3.2.2 Deep Foundations

Deep foundations, consisting of driven or drilled-in piles, can be used to support the proposed cargo facilities. Supporting the taxiway and aprons on deep foundations is not considered cost effective. We recommend that other methods be used to limit post construction settlement of slabs-on-grade, taxiways, and aprons. Deep foundations used to support buildings should extend through the waste and peat soils and bear in the underlying sand and gravel deposit. However, installing piles through the waste may be difficult due to the potential to encounter obstructions. Installation of drilled-in piles may accommodate obstructions somewhat better since the obstruction may be able to be removed using the drilling equipment.

Drilled-in piles should be designed to develop capacity as friction in the sand and gravel deposit with an allowable adhesion value of 500 psf. Downdrag loads on the piles from ongoing settlement of the waste or peat should be considered in the design. Downdrag loads should be expected to be large. Settlement of structures supported on deep foundations is estimated to be less than one inch with no long-term creep settlement.

The lowest level floor slabs can be constructed as structural slabs that are supported on deep foundations. Alternatively, the slabs can be constructed as slabs-on-grade provided the slabs are separated from the portion of the building supported on deep foundations and can tolerate both primary and long-term settlement of the underlying waste and/or peat. Since settlement of slabs-on-grade, without DDC or preloading, are estimated to be excessive, we do not recommend that building slabs be supported on grade.

The cost to install drilled-in piles will depend on the type, size, and capacity of the pile required. In addition, obstructions encountered during installation could significantly impact costs. For purposes of cost estimating, we recommend that a cost of $5,000 per 40-ton pile be used. Provided the pile capacity does not exceed 40 tons per pile, no load test will be required. For budgeting purposes, a mobilization cost of approximately $10,000 should be assumed. We anticipate that approximately 200 piles per building will be required which includes a structural slab at each building. This option would cost approximately 4 million dollars.

3.3 Preliminary Geotechnical Recommendations

Based on our understanding of the proposed site development, we recommend that the new cargo buildings, aprons, and portions of the taxiways be constructed following DDC treatment of the waste material and soil preloading of the peat deposit. DDC appears to be the most cost effective treatment of the waste based on the existing subsurface conditions and the proposed construction. In addition, since this area of the landfill will be cut to reach proposed grade, it is additionally recommended that DDC be conducted prior to the proposed cutting in order to reduce the required amount of site regrading.

Soil preloading should be used in conjunction with the planned filling to reach proposed grades. Approximately 6 to 20 feet of fill is proposed around the perimeter of the landfill which is where primarily peat was encountered and where the taxiways will be constructed. Site filling in these areas can be used as part of the preload program. Since it has been estimated that between 6 and 36 months will be required to allow the peat to adequately consolidate, we recommend that placement of the fill be done as early as possible.

Deep foundations, although technically feasible, are not recommended for support of the buildings at this time due to the anticipated high costs of construction. Use of deep foundations would be limited to the buildings only and additional costs would be incurred to treat the remainder of the site, i.e. aprons and taxiways. Since it is likely that the proposed buildings can be designed to withstand some settlement it does appear to be cost effective to treat the buildings separately and require additional treatment for the taxiways and aprons. As such, we recommend that the building façade be made of materials that will not as readily show the effects of settlement. A steel façade is expected to be more settlement tolerable than brick or concrete block. Regular maintenance of the buildings, aprons and taxiways should be expected to combat the effects of settlement.

Refer to **Table 3-1** for a summary of foundation alternatives.

3.4 Recommendations for Future Investigations

Prior to final design, we recommend that a thorough geotechnical subsurface investigation and laboratory testing program be conducted at the site. The program should be designed to supplement the information gathered as part of this study. Further characterization and laboratory testing of the waste and peat soils is required prior to final design.

3.4.1 Additional Test Borings

At the final location of the proposed cargo buildings, we recommend that up to 6 test borings be drilled within the footprint of each structure. If DDC or soil preloading alternatives are utilized, test borings should extend approximately 10 feet into the natural inorganic sand and gravel deposit underlying the site. If piles are utilized, test boring depths should extend into the underlying sand and gravel layer 20 feet beyond the proposed pile tip elevation.

For the proposed taxiways and aprons, up to 4 test borings per acre should be drilled. Test borings should be drilled to a depth approximately 10 feet into the underlying sand and gravel layer.

During future subsurface investigations the characteristics of the peat should be further investigated, including the peat underlying the landfill, around the perimeter of the landfill, and beyond the limits of the landfill where taxiways will be built. Geotechnical samples of the waste should also be obtained for laboratory testing. In

TABLE 3-1

SUMMARY OF FOUNDATION ALTERNATIVE EVALUATION

CARGO FACILITIES, T.F GREEN AIRPORT
RHODE ISLAND AIRPORT CORPORATION
WARWICK, RHODE ISLAND

Foundation Alternative	Application	Advantages	Disadvantages	Preliminary Estimated Cost	Schedule Impact
Deep Dynamic Compaction (DDC)	For use in areas underlain mostly by waste material (approx. 10 acres).	▪ Reduces post-construction primary settlement to approximately 12-inches. ▪ Decreases volume of in-place waste.	▪ Does not eliminate long-term creep settlement. ▪ Causes vibrations. ▪ Requires a large crane to work near existing runway. ▪ Maintenance of the buildings and aprons will be needed due to ▪ Regrading will be required following DDC. ▪ Not suitable for use on peat. ▪ Requires the use of a specialty contractor	$65,000 - $87,000 / acre	None
Soil Preloading	For use in areas underlain mostly by peat soils (approx. 10 acres).	▪ Reduces post-construction primary settlement to approximately 6-inches. ▪ Can be integrated with proposed site regrading.	▪ Does not eliminate long-term creep settlement. ▪ Impacts construction schedule ▪ Maintenance of the aprons and taxiways will be needed due to settlement. ▪ Excess fill material will need to be removed following preloading. ▪ Not suitable for use on waste material.	$250,000 / acre	Requires fill to remain in place for up to 36 months prior to construction.
Deep Foundations	For support of buildings only.	▪ Reduces post-construction settlement to less than 1-inch. ▪ Eliminates long-term creep settlement. ▪ "Best" long-term performance of buildings.	▪ Obstruction in the waste strata could significantly increase costs. ▪ Aprons and taxiways must be treated separately. ▪ Piles will have to penetrate landfill cover.	$1,000,000 / building	None

Recommended Alternative	Estimated Cost
▪ DDC over 10 acres	$650,000 - $870,000
▪ Preloading over 10 acres	$2,500,000
Total Cost $3,150,000 - $3,337,000	

addition, a small-scale field test to assess the compressibility of the waste may be required.

3.4.2Additional Laboratory Testing

Additional laboratory testing will be required to further investigate the properties of the waste and peat for the final design. Consolidation tests (ASTM D2435) should be conducted on undisturbed samples of the peat deposit to investigate the consolidation properties of the peat. Index testing, including grain size analysis (ASTM D422) and Atterberg limits (ASTM D4318) should be conducted on the peat and waste to further classify the properties of each strata. Further characterization of the waste should include an estimate of the percent of waste and soil observed in the samples collected and the degree of decomposition of the waste. Additionally, further organic content tests (ASTM D2974) should be conducted on both the waste and peat.

Section 4
Construction Considerations

4.1 General

The purpose of this section is to discuss issues related to geotechnical aspects of construction as they relate to the foundation support alternatives presented herein. Included are anticipated methods of construction and identification of potential related construction problems.

4.2 Deep Dynamic Compaction

Construction considerations for the use of DDC as a means to improve the settlement characteristics of the waste material at the site include the following:

- DDC involves the use of a large crane dropping a heavy weight from a large height. The use of this type of crane in close proximity to airplane traffic will have to be considered;
- Vibrations created during DDC will have to be monitored due to the proximity of the airport industrial facilities and residential properties to the site. Typically structures located more than 200 feet from the DDC operation do not experience damaging vibrations;
- DDC should be done prior to regrading and installation of the landfill cover;
- DDC is not expected to eliminate long-term creep settlement associated with decomposition of the waste located below the proposed buildings. This additional settlement will need to be incorporated into the design of the proposed structures. In addition, long-term creep settlement of the buildings and aprons should be monitored and maintenance will likely be needed over time.

4.3 Soil Preloading

Construction considerations for the use soil preloading as a means to improve the settlement characteristics of the peat deposit at the site include the following:

- Granular material suitable for use in a soil preload program is anticipated to be readily available;
- Placement of the preload material is anticipated to be accomplished with conventional earth moving equipment;
- Fill used as part of a preloading program should be placed in conjunction with site filling around the perimeter of the landfill and can be used for the landfill cover;

- A minimum of 10 feet of fill should be placed over the peat deposit. Larger amounts of fill may be used to expedite the consolidation process; and

- Preloading is not expected to eliminate long-term creep settlement associated with decomposition of the peat soils. This additional settlement will need to be incorporated into the design of the proposed structures. In addition, long-term creep settlement should be monitored and maintenance will likely be needed over time.

4.4 Deep Foundations

Construction considerations for the use deep foundation units as a means to support the proposed structures include the following:

- Obstructions may be encountered during the installation of piles. They type and size of obstructions could add significant costs and time to the construction schedule;

- Piles can be either driven or drilled-in. Driven piles will cause vibrations that will need to be monitored;

- Piles should be installed prior to installation of the landfill cover;

- Piles will have to penetrate through the landfill cover;

- Potentially large downdrag loads must be considered and incorporated into the design of the piles;

- A load test will be required if pile capacities exceed 40 tons; and

- Soil and waste cuttings produced during the installation of piles will need to be properly disposed of.

Subject: Limited Environmental Site Investigation Report
T. F. Green Airport
Former Truck Away Landfill Site
Warwick, Rhode Island

Dear Ms. Aschman:

On behalf of the Rhode Island Airport Corporation (RIAC), Camp Dresser & McKee, Inc. (CDM) hereby submits the enclosed Limited Environmental Site Investigation Report for the former Truk Away Landfill Site at the T. F. Green Airport in Warwick, Rhode Island. As we discussed previously, this initial investigation was not intended to provide a comprehensive assessment of the site. As agreed between RIAC, RIDEM and CDM, the goal of this preliminary investigation was to provide site environmental and geotechnical data so that RIAC can investigate the feasibility of constructing air cargo buildings at the site.

CDM is in the process of preparing a conceptual design and preliminary cost estimate for various closure/site improvement scenarios. Upon completion of this work, RIAC will evaluate the feasibility of future airport use of the site and will convey the results of this evaluation to the Rhode Island Department of Environmental Management and the Rhode Island Department of Administration.

Please call either of the undersigned at (617) 452-6000 if you have any questions or if you need additional information.

Very truly yours,

CAMP DRESSER & McKEE INC.

Matthew Dentch, P.E.
Project Manager

Section 1
Introduction

This Limited Environmental Site Investigation Report for the former Truk Away Landfill (the site) at the T. F. Green Airport in Warwick, Rhode Island has been prepared by Camp Dresser & McKee, Inc. (CDM) to document subsurface conditions at the site. The Rhode Island Airport Corporation (RIAC) is investigating the feasibility of constructing four 30,000 square foot cargo buildings on the landfill. In addition to the environmental investigation of the site, CDM undertook a geotechnical study of the site to evaluate the engineering properties of the subsurface soils. The geotechnical evaluation was prepared as a separate report in January 2001.

The investigation described herein was intended as an initial investigation of subsurface conditions at the site and was not meant to include a comprehensive site investigation of the landfill area. CDM undertook this limited investigation to take advantage of the field work being conducted for geotechnical purposes and to give RIAC and the Rhode Island Department of Transportation (RIDOT) preliminary data concerning whether landfill operations have impacted soil, groundwater and/or soil gas in this area. More comprehensive investigations will likely be required to provide adequate information for landfill closure. If RIAC chooses not to pursue cargo building construction at the landfill, responsibility for further landfill investigations and closure will revert back to RIDOT.

1.1 Site Description and History

The landfill area is bounded to the west and northwest by industrial property, to the north by the southern end of Runway 34-16, to the east by the wetlands at the end of the runway and a former City of Warwick dump, and to the south by residential property. The landfill covers approximately 24 acres and is almost completely surrounded by wetlands. The landfill surface is vegetated with low growing shrubs and grasses and occasional stands of small trees with maximum height of about 20 feet. Numerous piles and small areas of solid waste are located throughout the landfill, although no drums or containers that may store hazardous waste were noted on the ground surface during CDM's field investigations or site visits. A Locus Map is provided on **Figure 1-1** and a Site Plan is provided on **Figure 1-2**, contained in the report back pocket.

Correspondence from Truk-Away and Sanitas Waste Disposal to the Division of Solid Waste Management during the 1970's that have been made available to CDM suggests that the site is underlain by extensive deposits of peat. The waste materials placed in the landfill are not well documented but reference is made to "rubbish and construction demolition debris." The removal of batteries from the landfill has been reported to have occurred in the past. No evidence has been presented to CDM to suggest hazardous waste disposal has occurred at the site.

Section 2
Description of Field Activities

This section describes field activities conducted as part of this limited subsurface investigation, which included:

- excavation of test pits around the landfill perimeter to delineate the edge of waste
- wetland flagging
- advancement of soil borings, including the collection and laboratory analysis of soil samples
- installation of six monitoring wells
- monitoring well development
- groundwater sampling and laboratory analysis; and
- soil vapor monitoring.

2.1 Edge of Waste Delineation

To delineate the limits of waste at the landfill, TMC Services, Inc. of Bellingham, Massachusetts excavated test pits at 23 perimeter locations. Up to four test pits were excavated at each location until the approximate line of waste was encountered. Test pits were excavated on October 18 and October 19, 2000 with a CAT 426B backhoe and a CAT 315B excavator. Test pit depths varied from 0.5 feet to 12 feet below ground surface. A CDM representative monitored the test pits in the field. **Table 2-1** gives a summary of the conditions encountered in the test pits.

The approximate locations of the test pits and the approximate extent of waste are shown on **Figure 1-2**. Observations made during test pit excavations indicate that the limits of waste generally correspond to, and extend into, the edge of wetlands to the north and east and the fence line/property to the south and west.

2.2 Wetland Delineation

During August and September 2000, Applied Bio-Systems Inc. (ABS) of Kingston, Rhode Island delineated six wetland areas located at the site. The wetland flags were later field surveyed and are shown on Figure 1-2. The wetland delineation method employed follows the guidelines established by the Army Corps of Engineers 1987 Wetland Delineation Manual and RIDEM - Rules and Regulations Governing the Administration and Enforcement of the Freshwater Wetlands Act (April, 1998).

Wetland 1 (Flag Numbers 100-118) is a small wetland area located within an open area just inside of the property fence from the Industrial Drive entrance way. This wetland appears to have been created from excavation work and it may be classified by RIDEM as either an Area Subject to Flooding (ASF) or an Emergent Plant Community. The wetland area is contained within an area of fill soils and the dominant vegetation includes: wool grass (Scirpus cyperinus) and soft rush (Juncus

A brown to black fiborous peat was observed in Test Pits 15A, 16A and 17A

effusus). This wetland will probably be classified as an ASF since the vegetation within the wetland is so sparse and it appears to be flooded only during storm events. Regardless, the wetland area is too small to receive a 50-foot Perimeter Wetland. Sheet 60 of the Soil Survey of Rhode Island classifies this wetland area as having a Dumps (Du) soil unit. This soil unit consists of areas used for trash disposal (Rector, USDA, 1981)

Wetland 2 (Flag Numbers 200-205) is another small wetland area located just inside of the property fence from the Industrial Drive entranceway. This wetland also appears to have been created from excavation work. However, this wetland will likely be classified as an Emergent Plant Community by RIDEM. The wetland consists of fill soils and is dominated with plants, which include common reed (Phragmites australis) and purple loosestrife (Lythrum salicaria). The Soil Survey of Rhode Island classifies this wetland as having a Dumps (Du) soil unit, an area used for trash disposal. The wetland area is also too small to receive a 50-foot Perimeter Wetland.

Wetland 3 (Flag Numbers 300-313) is a wetland located adjacent to the southern edge of the existing pathway into the property. Also, this wetland area appears to have been created from past excavation activities. This wetland of fill soils and is predominately an Emergent Plant Community consisting of vegetation that includes common reed and purple loosestrife. The Soil Survey of Rhode Island classifies this wetland as having a Dumps (Du) soil unit, an area used for trash disposal. This wetland is also too small to receive a 50-foot Perimeter Wetland.

Wetland 4 (Flag Numbers 400-420) is a large wetland area located along the southern edge of the property. The majority of the wetland in the vicinity of the airport property consists largely of common reed. The Soil Survey of Rhode Island depicts the wetland area as an isolated wetland complex consisting of Sudbury sandy loam (Ss), a moderately well drained soil unit and Walpole sandy loam (Wa), a poorly drained soil unit. This wetland unit will likely be classify this as a Marsh with a 50 foot Perimeter Wetland extended from the biological (flagged) edge as area within RIDEM jurisdiction.

Wetland 5 (Flag Numbers 500-532) is a small wetland area located adjacent to the northern edge of the existing pathway into the property, opposite wetland 3. This wetland also may have been created from past excavation activities based on the uneven terrain. This wetland is dominated by plants that include: pussy willow (Salix discolor), soft rush, purple loosestrife, fox sedge (Carex vulpinoidea), and pale smartweed (Polygonum lapathifolium). The Soil Survey of Rhode Island classifies this wetland as having a Dumps (Du) soil unit, an area used for trash disposal. This wetland area will likely be classify as a Shrub Wetland and it is too small to receive a 50-foot Perimeter Wetland.

Wetland 6 (#s 600-655) is a large wetland complex located along the northern portion of the landfill area. The wetland area is associated with a large stream complex part

of Buckeye Brook. The stream will either have a 100 foot Riverbank Wetland (if the stream is less than 10 feet in width on average) or a 200 foot Riverbank Wetland (if the stream is greater than 10 feet in width on average) extended from the riverbank edge of the channel as area within RIDEM jurisdiction. The vegetated wetland area consists primarily of common reed, willow, sweet pepperbush (Clethra alnifolia), Japanese bamboo (Polygonum cuspidatum), and yellow birch (Betula alleghaniensis). The wetland is classified by RIDEM as a Wooded Swamp and will have a 50-foot Perimeter Wetland extended from the flagged edge.

2.3 Soil Boring Advancement

To define subsurface conditions within the limits of the site, New Hampshire Boring Inc. of Derry, New Hampshire advanced eight test borings (MW-1, SB-2, MW-3, SB-4, MW-5, MW-6, MW-7, MW-8) at the site from November 6 through November 22, 2000. A CDM representative monitored the test borings in the field .

The test borings were drilled using an all terrain vehicle (ATV) drill rig. All test borings fully penetrated the existing landfill soils and were terminated approximately 30 feet into the naturally deposited, inorganic sand and gravel stratum underlying the site. Test boring depths ranged from 32 feet to 77 feet below the existing ground surface.

Split-spoon sampling was conducted at five foot intervals at each boring location in accordance with ASTM D1586 (2-inch diameter sampler driven 24 inches by blows from a 140-pound hammer falling freely for a 30-inch drop). The number of blows required to drive the sampler each 6-inch increment was recorded and the Standard Penetration Resistance (N-value) was determined as the sum of the blows over the middle 12-inches of penetration. Soil samples were screened for the presence of volatile organic compounds (VOCs.) through use of a photoionization detector (PID).

Water levels in each test boring were estimated from the conditions of the samples obtained during drilling and by the observed water levels within the borehole at the time of drilling. Test borings, where monitoring wells were not installed (SB-2 and SB-4), were backfilled with a cement-bentonite grout to an elevation approximately 5 feet above the bottom of the landfill material. Waste material and spoil material was used to fill in the remainder of the two test borings. Material not used to backfill the hole was containerized in 55 gallon drums. Logs of the test borings, prepared by the driller and reviewed by CDM, are included in Appendix A. The approximate locations of the explorations are shown on Figure 1-2.

2.3.1 Subsurface Soil Conditions

Subsurface soil conditions were interpreted from the test borings conducted within and around the area of proposed construction and our understanding of the local geology. The test pits were not used to interpret the subsurface conditions, only to delineate the waste at the site. Test borings drilled within and around the perimeter of the landfill typically encountered waste and soils overlying naturally deposited

sand and gravel. Waste was encountered in all of the test borings with the exception of MW-6.

Landfill cover material, consisting of loose to medium dense tan fine to coarse sand with varying amounts of gravel and silt, was encountered in several of the borings taken within the limits of the landfill. Cover material was not encountered in perimeter test borings SB-4 and MW-7. Cover thickness ranged from 1 to 5 feet with N values ranging from 4 to 29.

Waste soils typically consisted of loose to very dense wood, paper, glass, metal, wire and plastic. Waste thickness ranged from 15 to 33 feet with N values ranging from 4 to 100 blows for 3 inches. In test borings MW-3, SB-4, MW-5, and MW-6 the waste extended into the underlying peat for a thickness ranging from 5 to 30 feet. Samples taken within the peat consisted of dark brown fibrous organic peat with varying amounts of waste, silt, and sand.

All of the test borings that encountered peat, with the exception of MW-3, contained waste mixed in with peat for the full depth of the stratum. MW-3 contained an additional 3 feet of peat not containing waste. In test borings MW-5 and MW-6, the waste extended into the underlying sands and gravels of the site for approximately 5 to 8 feet. Total waste thickness encountered within the test borings ranged from 20 to 40 feet. Test borings MW-1, SB-2, and MW-7, which did not encounter peat, were located in the most northern and eastern sections of the landfill, near the southern end of Runway 34-16 and along the wetlands to the east.

The natural inorganic soils encountered below the waste and peat deposits typically consisted loose to dense, gray, fine to coarse sand and gravel, with varying amounts of silt. The loose sand and gravel layer was typically encountered below the peat deposit. All test borings were terminated in the sand and gravel layer. The thickness of this layer was at least 32 to 42 feet.

A summary of subsurface material observed during boring advancement explorations is presented in **Table 2-2**. At each of the six boring locations where monitoring wells were installed, the soil sample with the highest PID reading from each boring was submitted to AMRO Laboratories for laboratory analyzed for total petroleum hydrocarbons (TPH) by EPA Method 418.1, VOCs by EPA Method 8260, semi-volatile organic compounds (SVOCs) by EPA Method 8270, pesticides by EPA Method 8081, PCBs by EPA Method 8082, Total Organic Carbon (TOC) and TAL metals by EPA Method 200/6000/7000 series.

Laboratory analysis results for soil samples are summarized on **Table 2-3**. A review of the data reveals that none of the soil samples contain VOCs, SVOCs or metals (except arsenic) in concentrations exceeding RIDEM industrial/commercial direct exposure or leachability criteria. Arsenic was reported at 17 mg/kg in the 20'-22' sample from MW-1, 9.1 mg/kg in the 10'-12' sample from MW-7 and at 6.8 mg/kg in the 45'-47' sample from MW-8. The RIDEM industrial/commercial direct exposure

I/C DEC - Industrial/Commercial Direct Exposure Criteria
Shaded values exceed RIDEM criteria, although the observed arsenic concentrations may be attributable to background conditions.

criteria for arsenic is 3.8 mg/kg. The concentrations of soil arsenic may be at background levels or no higher than other urban soils in the area.

None of the soil samples analyzed were reported to contain PCBs or pesticides above the laboratory method detection limit. Only one soil sample was reported to contain TPHs at a concentration above the laboratory method detection limit, the 10'-12' sample from MW-7 was reported to contain TPH at 54 micrograms per kilogram (ug/kg).

2.4 Monitoring Well Installation

Six monitoring wells were installed in completed boreholes MW-1, MW-3, MW-5, MW-6, MW-7, and MW-8 as part of the subsurface investigation. The monitoring wells were installed at depths ranging from 13 feet to 34 feet below ground surface. Ten foot screens were placed 7 feet below the measured ground surface level. The monitoring wells were backfilled with bentonite to the bottom of the screen.

Monitoring well screen was constructed of 2-inch diameter PVC with 0.020-inch machine-slots. Monitoring well riser was constructed of two inch threaded PVC. The well screen was backfilled using a sand pack to a level of three feet above the top of the screen interval. Sandpack was allowed to settle while slowly removing downhole tools. The remaining length of borehole was backfilled around the riser with bentonite and cement slurry. A road box was constructed approximately 2.5 feet above ground surface.

2.5 Groundwater Monitoring Well Development and Sampling

On November 28, 2000, the six newly installed monitoring wells were developed by evacuating a minumum of 50 gallons from each well. At each of the monitoring wells, groundwater appeared to be free of excess fines after the removal of 50 gallons. Well development water was containerized adjacent to each well in 55 gallon drums. On that date, floating product appeared to be present in MW-3 (approximately 2 feet in thickness) and MW-5 (less than ¼ inch in thickness). In addition, a strong landfill gas odor was noted from MW-1.

On December 13, 2000, CDM collected groundwater samples from each of the six newly installed monitoring wells. Prior to collecting groundwater samples, a minimum of three well volumes were removed from each well and containerized in a 55-gallon drum. In addition, purged water was field screened for temperature, specific conductance, dissolved oxygen and pH to document aquifer stabilization prior to sample collection. The groundwater samples were placed in appropriate glassware, kept in an iced cooler and transported to AMRO Environmental Laboratories.

Groundwater samples were analyzed for the following parameters: Hazardous Substance List (HSL) VOCs according to EPA Method 8260, semi-volatile organic compounds (SVOCs) according to EPA Method 8270, TAL metals by EPA Method 200/6000/7000 series, nitrate nitrogen, alkalinity, chemical oxygen demand, chlorides, total dissolved solids, total cyanide, sulfate, pesticides by EPA Method 8081, and PCBs by EPA Method 8082.

The laboratory analysis results for groundwater samples are summarized on **Table 2-4**. A review of the results indicates that two petroleum compounds were detected in groundwater samples above RIDEM GB groundwater objectives. The groundwater sample from MW-3 contained the greatest number of compounds detected and generally at the highest concentrations. As noted previously, a layer of free product measuring approximately 2 feet in thickness was detected on groundwater in this well. The two compounds detected in groundwater at MW-3 above RIDEM groundwater standards, with their concentration in parenthesis included: toluene (1,700 ug/l), and ethylbenzene (2,500 ug/l). Of all the VOCs detected, benzene and naphthalene were detected with the highest frequency, detected at concentrations exceeding RIDEM groundwater standards in five of the six monitoring wells.

None of the groundwater samples were reported to contain PCBs or pesticides above RIDEM groundwater standards. The parameters detected in site groundwater are typical of what might be expected at a landfill that accepted residential and commercial refuse. Exceedances of applicable GB criteria are few and sporadic. One concern is the appearance of floating material in MW-3, which may represent a continuing source of groundwater contaminants and may require further investigation. This concern is validated by a comparable mix of contaminants appearing in MW-8, (which is hydraulically down gradient from MW-3) including the only other GB criteria exceedance.

2.6 Determination of Groundwater Flow Direction

On December 13, 2000 and prior to well purging, CDM measured the depth to groundwater from the top of each of the six groundwater monitoring well casings. Since the elevation of each well casing was determined through field survey, groundwater elevations were determined by subtracting the depth to groundwater from the top of well casing. A summary of the groundwater elevation is presented on **Table 2-5**. A Groundwater Contour Map is presented on Figure 2-1 and indicates that site groundwater is flowing radially away from the center of the landfill to the north, east and south toward area wetlands

2.7 Soil Gas Probes

On November 15 and 16, 2000, CDM installed 16 vapor probes at the site to measure soil gas concentrations for landfill parameters. All vapor probes were driven down to a depth of four feet. After extracting the gas probe, Teflon tubing was then placed down the hole. Bentonite was packed around the tubing to create an air tight seal.

MW-7	20.6	4.68	15.92
MW-8	37.5	20.87	16.63

^ Elevations based on National Geoditical Vertical Datum.

Soil gas was extracted for five minutes before chemical concentrations were recorded. Vapor probe locations are shown on Figure 1-2. Vapor probes were installed around the landfill perimeter and on top of the landfill in the area of proposed cargo buildings. Portable gas monitoring equipment was used to determine the concentrations of hydrogen sulfide, methane, carbon dioxide, oxygen and VOCs in shallow soil gas.

A summary of the soil gas field screening is presented on **Table 2-6**. As expected at a landfill that has not been closed with a gas venting system, the screening results indicate that shallow soil gas at the site under vacuum contains elevated methane concentrations. These results are typical of landfill gas. As illustrated in Table 2-6, where methane, the indicator of decomposition is high, oxygen is low in concentration.

(1) No readings were collected at VP-6 due to wet conditions.
(2) Volatile organic compound (VOCs) readings were collected using a ThermoElectron Model 580B Organic Vapor Meter.
(3) Hydrogen sulfide readings were taken with an Interscan H2S Meter.
(4) All other readings were collected with a GEM 500 air monitoring device.

Section 3
Summary and Discussions

CDM conducted this Limited Environmental Subsurface Investigation of the Former Truk Away Landfill at the T.F. Green Airport in Warwick, Rhode Island. The investigation described in this report was intended as an initial investigation of subsurface conditions at the site and was not designed to include a comprehensive site investigation of the landfill area.

The Rhode Island Airport Corporation (RIAC) is investigating the feasibility of constructing four 30,000 square foot cargo buildings on the landfill. In conjunction with the environmental investigation of the site, CDM undertook a geotechnical study of the site to evaluate the engineering properties of the subsurface soils and to conduct a limited feasibility evaluation of foundation systems for the proposed buildings, taxiway and ramps. The geotechnical evaluation was prepared as a separate report in January 2001.

- Field activities conducted as part of this limited subsurface investigation included:
- excavation of test pits around the landfill perimeter to delineate the edge of waste;
- wetland flagging;
- advancement of soil borings, including the collection and laboratory analysis of soil samples
- installation of six monitoring wells;
- monitoring well development
- groundwater sampling and laboratory analysis; and
- soil vapor monitoring.

Key findings of the investigation included:

- The landfill's edge of waste generally corresponded to the site's fence line/property line to the south and west and with the edge of wetlands to the north and east.

- The soil and groundwater laboratory analysis results and field screening of soil vapor indicates that subsurface conditions at the site are typical of what would be expected at a landfill containing residential and/or commercial waste. The only compound detected in soil above RIDEM Industrial/Commercial Direct Exposure or Leachability Criteria was arsenic at two locations. The concentrations of arsenic detected (9.1 mg/kg and 6.8 mg/kg) could in fact be attributable to background conditions and are within the range of a typical urban fill. The only compounds detected in groundwater samples at or above RIDEM GB Groundwater Objectives were toluene at 1.7 mg/l in MW-3 and ethylbenzene at 2.5 mg/l in MW-3 and 2.1 mg/l in MW-8. Floating product, however, was detected at a thickness of about 2

feet in MW-3 which is located in the center of the landfill. As expected at a landfill of this nature, high concentrations of methane was detected in soil gas at the site.

Given the potential future use of this site as a location for air cargo buildings, the following issues should be addressed:

1. Since filling activities have been reported as recently as 1995, it is believed that regulations require a final landfill cover. Landfill closure components would include: a cover system, a landfill gas venting system and perimeter drainage. It is important to note that a significant portion of the landfill closure elements will also be elements of site development. For example, the observed high methane in soil gas would require a venting system to vent landfill gases away from work areas at the site. Also, a significant portion of the site will require grading to construct the cargo buildings at a desirable grade. Lastly, wetland areas to the north and east will have to be filled to ensure proper side slope stabilization and surface drainage collection, key elements to any landfill closure. It is likely that RIAC would have to replicate an area equivalent to the filled area either at or near the airport or within Warwick city limits. These three items would be required regardless of application of RIDEM landfill closure requirements. Final requirements for landfill closure should be detailed after discussions with RIDEM officials.

2. The feasibility of RIAC constructing cargo buildings at the landfill is dependent on the cost associated with addressing geotechnical and environmental issues. A preliminary cost estimate to address the geotechnical issues was presented in a separate document. In order to prepare a preliminary estimate of the cost associated with landfill closure requirements contrasted against the cost that would be incurred due to site development as noted above, CDM recommends a meeting with regulatory officials to discuss RIDEM's requirements for landfill closure. Once these requirements are discussed, CDM will proceed with a conceptual design of the proposed site development and estimate the cost associated with landfill closure elements that would not otherwise be part of site development.

3. In addition to the wetland filling that will be required to ensure proper landfill closure to the north and east, the construction of a taxiway from Runway 34-16 to the proposed cargo buildings will also require wetlands filling due north of the landfill. CDM recommends a meeting with RIDEM to discuss this issue, including consideration of a potential compensatory wetland construction program within Warwick city limits to off-set the wetland impacts from the proposed cargo building project.

4. The floating product detected in MW-3 should be further investigated to determine the extent of floating product at the site. In addition, a sample of the product should be collected and identified by laboratory techniques (i.e.,

fingerprint analysis or petroleum identification) as to the type of product on site groundwater in MW-3.

RE: RIAC

Order No.: 0012182

Dear Matt Dentch:
AMRO Environmental Laboratories Corp. received 7 samples on 12/14/00 for the analyses presented in the following report.

AMRO operates a Quality Assurance Program which meets or exceeds National Environmental Laboratory Accreditation Conference (NELAC), state, and EPA requirements. A copy of the appropriate state and/or NELAC Certificate is attached. Please see the enclosed Case Narrative for quality control deviations that were encountered during the analyses associated with this project.

The enclosed Sample Receipt Checklist details the condition of your sample(s) upon receipt. Please be advised that any unused sample volume and sample extracts will be stored for a period of thirty (30) days from this report date. After this time, AMRO will properly dispose of the remaining sample(s). If you require further analysis, or need the samples held for a longer period, please contact us immediately.

This report consists of a total of 160 pages. This letter is an integral part of your data report. If you have any questions regarding this project in the future, please refer to the Order Number above.

Sincerely,

Nancy Stewart
Vice President / Lab Director

SAMPLE RECEIPT CHECKLIST

AMRO Environmental Laboratories Corporation

SAMPLE RECEIPT CHECKLIST

111 Herrick Street
Merrimack, NH 03054
(603) 424-2022

Client: CDM
Project Name: RIAC
Ship via: (circle one) Fed Ex., UPS, AMRO Courier,
and Del., Other Courier, Other:

AMRO ID: 00/2182
Date Rec.: 12-14-00
Date Due: 12-27-00

Items to be Checked Upon Receipt	Yes	No	NA	Comments
1. Army Samples received in individual plastic bags?			✓	
2. Custody Seals present?			✓	
3. Custody Seals Intact?			✓	
4. Air Bill included in folder if received?			✓	
5. Is COC included with samples?	✓			(in 3 coolers)
6. Is COC signed and dated by client?	✓			50
7. Laboratory receipt temperature.				TEMP = 2° + 2°
Samples rec. with ice ✓ ice packs ___ neither ___				
8. Were samples received the same day they were sampled?		✓		
Is client temperature 4°C ± 2°C?	✓			
If no obtain authorization from the client for the analyses.				
Client authorization from: Date: Obtained by:				
9. Is the COC filled out correctly and completely?	✓			
10. Does the info on the COC match the samples?	✓			
11. Were samples rec. within holding time?	✓			No 3 later than used
12. Were all samples properly labeled?	✓			
13. Were all samples properly preserved?	✓			
14. Were proper sample containers used?	✓			
15. Were all samples received intact? (none broken or leaking)	✓			
16. Were VOA vials rec. with no air bubbles?	✓			
17. Were the sample volumes sufficient for requested analysis?	✓			
18. Were all samples received?		✓		see fax
19. VPH and VOA Soils only:			✓	
Sampling Method VPH (circle one): M=Methanol, E=EnCore (air-tight container)				
Sampling Method VOA (circle one): M=Methanol, SB=Sodium Bisulfate, E=EnCore, B=Bulk				
If M or SB:				
Does preservative cover the soil?				
If NO then client must be faxed.				
Does preservation level come close to the fill line on the vial?				
If NO then client must be faxed.				
Were vials provided by AMRO?				
If NO then weights MUST be obtained from client				
Was dry weight aliquot provided?				
If NO then fax client and inform the VOA lab ASAP.

STATE CERTIFICATE

State of New Hampshire
Environmental Laboratory Accreditation Program

Awards Primary Accreditation to

AMRO Environmental Laboratories
of
Merrimack, NH

For the analyses listed on the attached page(s) in accordance with the provisions of the NELAC Standards and Env-C 300.

Certificate Number: 100100-C

Date of Issue: January 24, 2001

Expiration Date: July 19, 2001

Program Manager

Continuing accreditation status is dependent on successful ongoing participation in the program.
Customers may verify the laboratory's current status by calling (603) 271-2991 or (603) 271-2998

NEW HAMPSHIRE ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM

Laboratory: AMRO Environmental Laboratories Address: Merrimack, NH
Certificate Number: 100100-C Date of Issue: January 24, 2001 Expiration Date: July 19, 2001

ACCREDITS THE ABOVED MENTIONED LABORATORY FOR THE FOLLOWING ANALYSES:

(ANALYSES IN **UNDERLINED BOLD** ARE NOT EPA APPROVED FOR COMPLIANCE TESTING)

DRINKING WATER METALS

Aluminum:	EPA 200.7
Antimony:	EPA 200.7, EPA 200.9
Arsenic:	EPA 200.7, EPA 200.9
Barium:	EPA 200.7
Beryllium:	EPA 200.7, EPA 200.9
Cadmium:	EPA 200.7, EPA 200.9
Calcium:	EPA 200.7
Chromium:	EPA 200.7, EPA 200.9
Copper:	EPA 200.7, EPA 200.9
Iron:	EPA 200.7, EPA 200.9
Lead:	EPA 200.7, EPA 200.9
Mercury:	EPA 245.1
Nickel:	EPA 200.7, EPA 200.9
Selenium:	EPA 200.9
Silver:	EPA 200.7, EPA 200.9
Sodium:	EPA 200.7
Thallium:	EPA 200.9
Zinc:	EPA 200.7

DRINKING WATER INORGANIC CONTAMINANTS

Alkalinity:	**EPA 310.1**
Chloride	EPA 300.0, EPA 325.3
Chlorine, Total Residual:	SM 4500Cl G mod.
Chlorine, Free Residual:	SM 4500Cl G mod.
Conductivity	EPA 120.1
Cyanide, Total:	SM 4500-CN E
Fluoride	EPA 300.0, EPA 340.2
Fluoride	SM 4500-F E
Hardness by Calculation:	EPA 200.7
Nitrate-N:	EPA 353.2
Nitrite-N:	EPA 353.2
Orthophosphate	EPA 300.0
pH:	EPA 150.1
Sulfate	**EPA 375.4**, EPA 300.0
Total Filt. Residue (TDS):	SM 2540C
Turbidity:	EPA 180.1

INDIVIDUAL DRINKING WATER ORGANIC CONTAMINANTS

DBCP:	EPA 504.1
EDB:	EPA 504.1

WASTEWATER METALS

Aluminum:	EPA 200.7

WASTEWATER METALS Cont.)

Antimony:	EPA 200.7, EPA 204.2
Arsenic:	EPA 200.7, D297293C

NEW HAMPSHIRE ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM

Laboratory: AMRO Environmental Laboratories Address: Merrimack, NH
Certificate Number: 100100-C Date of Issue: January 24, 2001 Expiration Date: July 19, 2001

ACCREDITS THE ABOVED MENTIONED LABORATORY FOR THE FOLLOWING ANALYSES:

WASTEWATER INORGANIC CONTAMINANTS (cont.)

TKN:	EPA 351.1
Total Phosphorus:	EPA 365.2
Total Phenolics:	EPA 420.1

PCBs IN WASTEWATER

PCB-Aroclor 1016:	EPA 608
PCB-Aroclor 1221:	EPA 608
PCB-Aroclor 1232:	EPA 608
PCB-Aroclor 1242:	EPA 608
PCB-Aroclor 1248:	EPA 608
PCB-Aroclor 1254:	EPA 608
PCB-Aroclor 1260:	EPA 608

PESTICIDES IN WASTEWATER

Aldrin:	EPA 608
a-BHC:	EPA 608
b-BHC:	EPA 608
d-BHC	EPA 608
g-BHC (Lindane):	EPA 608
Chlordane:	EPA 608
4,4'-DDD:	EPA 608
4,4'-DDE:	EPA 608
4,4'-DDT:	EPA 608
Dieldrin:	EPA 608
Endosulfan I:	EPA 608
Endosulfan II:	EPA 608
Endosulfan Sulfate:	EPA 608
Endrin:	EPA 608
Endrin Aldehyde:	EPA 608
Heptachlor:	EPA 608
Heptachlor Epoxide:	EPA 608

VOLATILE ORGANICS IN WASTEWATER

Benzene:	EPA 624
Bromodichloromethane:	EPA 624
Bromoform:	EPA 624
Bromomethane:	EPA 624
Carbon Tetrachloride:	EPA 624
Chloroethane:	EPA 624
Chloroform:	EPA 624
Chloromethane:	EPA 624
1,2-Dichlorobenzene:	EPA 624
1,3-Dichlorobenzene:	EPA 624
1,4-Dichlorobenzene	EPA 624
1,1-Dichloroethane:	EPA 624

VOLATILE ORGANICS IN WASTEWATER (Cont.)

1,2 Dichloroethane:	EPA 624
1,1-Dichloroethene:	EPA 624
t-1,2-Dichloroethene:	EPA 624
1,2-Dichloropropane:	EPA 624
t-1,3-Dichloropropene:	EPA 624
Ethylbenzene:	EPA 624
Methylene Chloride:	EPA 624
Tetrachloroethene:	EPA 624
1,1,2,2-Tetrachloroethane:	EPA 624
Toluene:	EPA 624
1,1,1 Trichloroethane:	EPA 624
1,1,2-Trichloroethane:	EPA 624
Trichloroethene:	EPA 624
Trichlorofluoromethane:	EPA 624
Vinyl Chloride:	EPA 624

WASTEWATER SEMIVOLATILE ORGANICS

Acenaphthene:	EPA 625
Anthracene:	EPA 625
Benzidine:	EPA 625
Benzo(a)anthracene:	EPA 625
Benzo(b)fuoranthene:	EPA 625
Benzo(a)pyrene:	EPA 625
Benzyl butyl phthalate:	EPA 625
Bis(2-chloroethyl) ether:	EPA 625
Bis(2-chloroethoxy) methane:	EPA 625
Bis(2-chloroisopropyl) ether:	EPA 625
Bis(2-ethylhexyl) phthalate:	EPA 625
4-Bromophenyl phenyl ether:	EPA 625
4-Chloro-3-methylphenol:	EPA 625
2-Chloronaphthalene:	EPA 625
2-Chlorophenol:	EPA 625
4-Chlorophenyl phenyl ether:	EPA 625
Chrysene:	EPA 625
Di-n-butyl phthalate:	EPA 625
Di-n-octyl phthalate:	EPA 625
3,3-Dichlorobenzidine:	EPA 625
2,4-Dichlorophenol:	EPA 625
Diethyl phthalate:	EPA 625
Dimethyl phthalate:	EPA 625
2,4-Dimethylphenol:	EPA 625
2,4-Dinitrophenol:	EPA 625
2,4-Dinitrotoluene:	EPA 625
2,6-Dinitrotoluene:	EPA 625
Fluoranthene:	EPA 625
Hexachlorobenzene:	EPA 625
Hexachlorobutadiene:	EPA 625

This certificate supercedes all previously issued certificates.

CASE NARRATIVE

CASE NARRATIVE
0012182

GENERAL

1. Some of the samples were received with broken containers. The client was contacted and instructed the laboratory to do analyses with what ever could be salvaged from the coolers.

2. Some of the samples were received not properly preserved for Total Cyanide and Metals analyses. Additional amount of preservatives (sodium hydroxide for total cyanide and nitric acid for the metals) was added prior analyzing the samples.

3. No other QC deviations were observed.

GC/MS-VOLATILES
WATER

1. The method blank (MBLK-12/27/00) contained Carbon disulfide at 0.93 µg/L below the reporting limit of 2.0 µg/L.

2. The samples MW-8 (0012182-02B) and MW-3 (0012182-05B) both have raised reporting limits due to sample dilution.

3. The pH for sample MW-6 (0012182-03E) was 6 above the recommended pH =<2.

4. The Matrix Spike (MS) and Matrix Spike Duplicate (MSD) were performed on sample MW-1 (0012182-01E. All %R's and %RPD's were within the laboratory control limits with the following exception:

    4.1 The compound Chlorobenzene recovered below the laboratory control limits (84-120%) in both the MS and MSD.

5. No other QC deviations were observed.

GC/MS-SEMIVOLATILES
WATER

1. The surrogate 2-fluorophenol recovered above the laboratory control limits (23-69%) in the following samples: MW-8 (0012182-02F), MW-3 (0012182-05F), and DUP-1 (0012182-07F) probably due to matrix interference.

2. The method blank (MB-3402) contained Bis (2-ethylhexyl) phthalate at 2.22µg/L below the reporting limit of 10µg/L.

3. The Matrix Spike Duplicate was not performed on sample MW-7 (0012182-04F) due to insufficient sample volume.

4. No other QC deviations were observed.

GC/ECD-PESTICIDES
WATER

1. The Matrix Spike Duplicate (MSD) was not performed due to insufficient sample volume. The Laboratory Control Sample (LCS) and Laboratory Control Sample Duplicate (LCSD) are provided.

2. Samples MW-8 (0012182-07F) and DUP-1 (0012182-07G) had reported recoveries for the surrogate Tetrachloro-m-xylene at 0% due to co-elution of non-target matrix interference. The surrogate could not be accurately integrated in the appropriate window.

3. The Matrix Spike (MS) was performed on sample MW-6 0012182-03G). All %R's were with in laboratory control limits with the following exceptions:

    3.1 The spike compound Heptachlor recovered above the laboratory control limits (1-164%) at 214% due to non-target matrix interference.

    3.2 The surrogate Tetrachloro-m-xylene recovered above laboratory control limits (40-117%) at 119%.

4. The Laboratory Control Sample (LCS-3407) and Laboratory Control Sample Duplicate (LCSD-3407) samples had all %R's and %RPD's within laboratory control limits with the following exceptions:

    4.1 The %RPD for Gamma-BHC was above the laboratory control limit of 15% at 17.1%.

5. No other QC deviations were observed.

GC/ECD-PCB
WATER

1. The batch Matrix spike (MS) was performed on sample 0012191-06A. All %R's are with in laboratory control limits with the following exception:

    1.1 The surrogate Decachlorobiphenyl recovered above the laboratory control limits (32-111%) at 124%.

2. The Matrix Spike Duplicate (MSD) was not performed due to insufficient sample volume.

3. No other QC deviations were observed.

METALS – WATER

1. The Method Blank (MB) had Zinc concentration at 19.41µg/L below the reporting limit 20µg/L.

2. Sample MW-1 (0012181-01C) had analytical (post digestion) spike recovery for Lead outside the acceptance 85-115% limits at 45.8%. To avoid dilution of the sample to the undetected level Lead concentration was determined by the Method of Standard Addition (MSA).

3. No other QC deviations were observed.

WET CHEMISTRY

1. All samples were analyzed for Nitrates outside the EPA recommended holding time (48 hours).

2. Sample MW-1 (0012182-01D) had Matrix Spike Duplicate (MSD) recovery outside the acceptance limits for Chloride. This failure was possibly due to high sample concentration relative to the spike concentration.

3. No QC deviations were observed.

tert-Butylbenzene	ND	2.0	µg/L
1,2,4-Trimethylbenzene	ND	2.0	µg/L
sec-Butylbenzene	ND	2.0	µg/L
4-Isopropyltoluene	ND	2.0	µg/L

Qualifiers:
ND - Not Detected at the Reporting Limit
J - Analyte detected below quantitation limits
RL - Reporting Limit; defined as the lowest concentration the laboratory can accurately quantitate.
S - Spike Recovery outside accepted recovery limits
R - RPD outside accepted recovery limits
B - Analyte detected in the associated Method Blank
NA - Not applicable where J values or ND results occur

Qualifiers:

ND - Not Detected at the Reporting Limit

J - Analyte detected below quantitation limits

B - Analyte detected in the associated Method Blank

* - Value exceeds Maximum Contaminant Level

S - Spike Recovery outside accepted recovery limits

R - RPD outside accepted recovery limits

E - Value above quantitation range

- See Case Narrative

RL - Reporting Limit; defined as the lowest concentration the laboratory can accurately quantitate.

RE: RIAC- TF Green Airport

Order No.: 0011179

Dear Matt Dentch:

AMRO Environmental Laboratories Corp. received 5 samples on 11/16/00 for the analyses presented in the following report.

AMRO operates a Quality Assurance Program which meets or exceeds EPA and state requirements. A copy of the appropriate State Certificate is attached. The enclosed Sample Receipt Checklist details the condition of your sample(s) upon receipt. Please see the enclosed Case Narrative for quality control deviations that were encountered during the analyses associated with this project.

Please be advised that any unused sample volume and sample extracts will be stored for a period of thirty (30) days from this report date. After this time, AMRO will properly dispose of the remaining sample(s). If you require further analysis, or need the samples held for a longer period, please contact us immediately.

This letter is an integral part of your data report. If you have any questions regarding this project in the future, please refer to the Order Number above.

Sincerely,

Nancy Stewart
Vice President / Lab Director

Dibenzofuran	ND	300		µg/Kg-dry	1	11/20/00 7:13:00 PM

Qualifiers:

ND - Not Detected at the Reporting Limit
J - Analyte detected below quantitation limits
B - Analyte detected in the associated Method Blank
* - Value exceeds Maximum Contaminant Level
S - Spike Recovery outside accepted recovery limits
R - RPD outside accepted recovery limits
E - Value above quantitation range
- See Case Narrative
RL - Reporting Limit; defined as the lowest concentration the laboratory can accurately quantitate.

Dear Laboratory Director:

Retain this letter for your records.

This letter is to inform you that there has been legislative changes made in the laboratory licensure renewal cycle. The laboratory license expiration date has been changed to December 30, of the appropriate year.

Therefore, your current license will remain in effect until December 30, 2000.

You will receive a new license renewal form approximately 8 weeks before your license is due to expire.

If you have any questions regarding the new license renewal format, please call me at (401) 222-1999.

Sincerely,

Ewa King

CASE NARRATIVE

CASE NARRATIVE
0011179

GENERAL

1. The samples were received in the laboratory at 1°C outside the recommended temperature of 4°C ± 2°C.

2. No other QC deviations were observed.

GC/MS-VOLATILES

1. The method blank-11/17/00 contained sec-Butylbenzene at 14 µg/Kg below the reporting limit of 25 µg/Kg and Carbon disulfide at 30 µg/Kg below the reporting limit of 50 µg/Kg.

2. No other QC deviations were observed.

GC/MS-SEMIVOLATILES

1. The batch Matrix Spike (MS) and Matrix Spike Duplicate (MSD) were performed on sample 0011177-01A. All %R's and %RPD's were within laboratory control limits with the following exception:

    1.1 The spike compound 2,4-Dinitrotoluene recovered below the laboratory limits (29-105%) at 23.1% in the MS.

2. No other QC deviations were observed.

GC-ECD-PESTICIDES

1. The Endrin Ketone %difference (%D) in the opening Continuing Calibration Verification analyzed on 11/21/00 exceeded the ±15% limit. The laboratory used the average percent difference for all analytes as per SW-846 Method 8081A Section 7.5. Please refer to the Continuing Calibration Summary Form in the Pesticide Section.

2. The closing continuing calibration verification standard (CCV) analyzed on 11/21/00 had the compound Endrin Ketone outside the acceptance criteria (±15%).

3. The laboratory control sample LCS-3186 had all %R's with in laboratory control limits with the following exceptions:

   3.1 The spike compound Heptachlor recovered below the laboratory control limits (47-137%) at 43.6%.

   3.2 The surrogate Tetrachloro-m-xylene recovered below the laboratory control limits (50-150%) at 45.1%.

4. No other QC deviations were observed.

GC/ECD-PCB

1. The Matrix Spike (MS) and Matrix Spike Duplicate (MSD) were performed on sample MW6 S-11 (0011179-01A). All %R's and %RPD's were with in laboratory control limits with the following exceptions:

   1.1 The spike compound Aroclor 1016 recovered below the laboratory control limits (41-125%) in the MSD at 38.8%.

1. The surrogate Tetrachloro-m-xylene recovered below the laboratory limits (43-117%) in the MSD at 39.8%.

2. The %RPD's for Aroclor 1016 and 1260 were above the laboratory control limit of 50%.

2. No other QC deviations were observed.

METALS – SOIL

3. Batch QC sample (0011229-04B) had Matrix Spike (MS) recoveries outside the acceptance limits for Aluminum, Barium, Calcium and Zinc and Matrix Spike Duplicate (MSD) recoveries outside the acceptance limits for Aluminum, Calcium, Iron and Potassium as well as %RPD – outside the acceptance limits for Calcium. These failures were possibly due to high concentration of Aluminum, Calcium and Iron in sample relative to spike concentration and sample non-homogeneity.

4. Laboratory Control Sample (LCS) recoveries for all analytes were within acceptance limits.

5. No other QC deviations were observed.

WET CHEMISTRY

1. No QC deviations were observed.

RE: 26553 RIAC TF Green Airport

Order No.: 0011255

Dear Matt Dentch:

AMRO Environmental Laboratories Corp. received 4 samples on 11/22/00 for the analyses presented in the following report.

The enclosed results are additional analyses requested after the original report was issued. AMRO operates a Quality Assurance Program which meets or exceeds EPA and state requirements. A copy of the appropriate State Certificate is attached. The enclosed Sample Receipt Checklist details the condition of your sample(s) upon receipt.

Please be advised that any unused sample volume and sample extracts will be stored for a period of thirty (30) days from this report date. After this time, AMRO will properly dispose of the remaining sample(s). If you require further analysis, or need the samples held for a longer period, please contact us immediately.

This letter is an integral part of your data report. If you have any questions regarding this project in the future, please refer to the Order Number above.

Sincerely,

Nancy Stewart
Vice President / Lab Director

APR 28 2000

Dear Laboratory Director:

Retain this letter for your records.

This letter is to inform you that there has been legislative changes made in the laboratory licensure renewal cycle. The laboratory license expiration date has been changed to December 30, of the appropriate year.

Therefore, your current license will remain in effect until December 30, 2000.

You will receive a new license renewal form approximately 8 weeks before your license is due to expire.

If you have any questions regarding the new license renewal format, please call me at (401) 222-1999.

Sincerely,

Ewa King

RE: **License Number 105**

Dear Ms. Stewart:

This is to acknowledge acceptance of the Analytical Laboratory License Renewal Application for the period of July 1, 1998 until June 30, 2000.

In accordance with the provisions of Chapter 23-16.2-A/LAB of the Rhode Island General Laws 1956, as amended, the Rhode Island Department of Health hereby issues this license renewal for the period as specified above, authorizing the operation and maintenance of this facility known as **AMRO Environmental Lab Corp.**

This license covers the premise located at:

111 Merrick St.
Merrimack, New Hampshire 03054

Sincerely,

Wayne I. Farrington

CASE NARRATIVE

CASE NARRATIVE
0011255

GENERAL

1. No QC deviations were observed.

GC/MS-VOLATILES
SOIL

1. No QC deviations were observed.

GC/MS-SEMIVOLATILES
SOIL

1. Sample MW3 S-15 (0011255-02A) had all surrogate recoveries outside the laboratory control limits possibly due to an error in spiking the sample surrogates. None of the target analytes were detected.

2. No other QC deviations were observed.

GC/ECD-PESTICIDES
SOIL

1. No QC deviations were observed.

GC/ECD-PCB
SOIL

1. No QC deviations were observed.

METALS – SOIL

1. Batch QC sample (0011266-01C) had Matrix Spike (MS) recoveries outside the acceptance limits for Aluminum, Copper, Iron, Lead and Zinc and Matrix Spike Duplicate (MSD) recoveries outside the acceptance limits for Aluminum, Barium, Iron, Lead and Zinc as well as %RPD – outside the acceptance limits for Iron and Zinc. These failures were possibly due to high concentration of Aluminum, Iron and Zinc in sample relative to spike concentration and sample non-homogeneity.

2. Batch QC sample (0011229-04B) had Matrix Spike (MS) and Matrix Spike Duplicate (MSD) recoveries outside the acceptance limits for Mercury possibly due to the sample matrix interference.

3. Laboratory Control Sample (LCS) recoveries for all analytes were within acceptance limits.

4. No other QC deviations were observed.

WET CHEMISTRY

1. No QC deviations were observed.

GC/MS VOLATILES- SOIL

Qualifiers:

ND - Not Detected at the Reporting Limit
J - Analyte detected below quantitation limits
B - Analyte detected in the associated Method Blank
* - Value exceeds Maximum Contaminant Level
S - Spike Recovery outside accepted recovery limits
R - RPD outside accepted recovery limits
E - Value above quantitation range
- See Case Narrative
RL - Reporting Limit; defined as the lowest concentration the laboratory can accurately quantitate.

2,4-Dinitrotoluene	ND	270		µg/Kg-dry	1	11/30/00 4:28:00 PM
Dibenzofuran	ND	270		µg/Kg-dry	1	11/30/00 4:28:00 PM

Qualifiers:

ND - Not Detected at the Reporting Limit
J - Analyte detected below quantitation limits
B - Analyte detected in the associated Method Blank
* - Value exceeds Maximum Contaminant Level
S - Spike Recovery outside accepted recovery limits
R - RPD outside accepted recovery limits
E - Value above quantitation range
- See Case Narrative

RL - Reporting Limit; defined as the lowest concentration the laboratory can accurately quantitate.

RE: RIAC TF GREEN AIRPORT Order No.: 0011123

Dear Matt Dentch:

AMRO Environmental Laboratories Corp. received 2 samples on 11/10/00 for the analyses presented in the following report.

AMRO operates a Quality Assurance Program which meets or exceeds EPA and state requirements. A copy of the appropriate State Certificate is attached. The enclosed Sample Receipt Checklist details the condition of your sample(s) upon receipt. Please see the enclosed Case Narrative for quality control deviations that were encountered during the analyses associated with this project.

Please be advised that any unused sample volume and sample extracts will be stored for a period of thirty (30) days from this report date. After this time, AMRO will properly dispose of the remaining sample(s). If you require further analysis, or need the samples held for a longer period, please contact us immediately.

This letter is an integral part of your data report. If you have any questions regarding this project in the future, please refer to the Order Number above.

Sincerely,

Nancy Stewart
Vice President / Lab Director

Dear Laboratory Director:

Retain this letter for your records.

This letter is to inform you that there has been legislative changes made in the laboratory licensure renewal cycle. The laboratory license expiration date has been changed to December 30, of the appropriate year.

Therefore, your current license will remain in effect until December 30, 2000.

You will receive a new license renewal form approximately 8 weeks before your license is due to expire.

If you have any questions regarding the new license renewal format, please call me at (401) 222-1999.

Sincerely,

Ewa King

1. No QC deviations were observed.

GC/MS-VOLATILES

1. The method blank-11/15/00 contained sec-Butylbenzene at 14µg/Kg below the reporting limit of 25µg/Kg.

2. No other QC deviations were observed.

GC/MS-SEMIVOLATILES

1. The laboratory control sample LCS-3181 had all %R's within laboratory control limits with the following exception:

    1.1 The Acenaphthene recovered below the laboratory control limits (55-95%) at 53.5%.

2. No other QC deviations were observed.

GC-ECD-PESTICIDES

1. The closing continuing calibration verification standard (CCV) analyzed on 11/17/00 had the compounds 4,4-DDT and Methoxychlor outside the acceptance criteria (±15%).

2. No other QC deviations were observed.

GC/ECD-PCB

1. No QC deviations were observed.

METALS – SOIL

1. Batch QC sample (0011131-01B) had Matrix Spike (MS) and Matrix Spike Duplicate (MSD) recoveries outside the acceptance limits for Aluminum as well as Matrix Spike (MS) recovery outside the acceptance limits for Iron. These failures were due to high concentration of Aluminum and Iron in sample relative to spike concentration.

2. Laboratory Control Sample (LCS) recoveries for all analytes were within acceptance limits.

3. No other QC deviations were observed.

WET CHEMISTRY

1. No QC deviations were observed.

GC/MS VOLATILES

Qualifiers:
ND - Not Detected at the Reporting Limit
J - Analyte detected below quantitation limits
B - Analyte detected in the associated Method Blank
* - Value exceeds Maximum Contaminant Level
S - Spike Recovery outside accepted recovery limits
R - RPD outside accepted recovery limits
E - Value above quantitation range
- See Case Narrative
RL - Reporting Limit; defined as the lowest concentration the laboratory can accurately quantitate.

METHOD BLANK

LEGEND

- VP-14 — VAPOR PROBE
- EDGE OF WETLAND
- TP-1 — DESIGNATION AND APPROXIMATE LOCATION OF TEST PIT EXCAVATED BY TCM SERVICES, INC.,
- SB-4 — DESIGNATION AND APPROXIMATE LOCATION OF TEST BORING DRILLED BY NEW HAMPSHIRE BORING INC.
- APPROXIMATE LIMITS OF PROPOSED BUILDINGS
- A — A' — LOCATION AND ORIENTATION OF GEOLOGIC CROSS SECTION A-A' SHOWN ON FIGURE 2-2
- EDGE OF WATER

NOTES

1.) BASE PLAN PREPARED FROM A DRAWING ENTITLED "TOPOGRAPHIC & BOUNDARY SURVEY OF LANDFILL AREA SOUTH OF T.F. GREEN AIRPORT", PREPARED BY BRYANT ASSOCIATES, INC., DATED JANUARY, 2001

2.) TEST PITS TP-1 THROUGH TP-23 WERE EXCAVATED BY TCM SERVICES' INC. OF BELLINGHAM, MASSACHUSETTS, ON OCTOBER 18 & 19 2000

3.) TEST BORING WERE DRILLED BY NEW HAMPSHIRE TEST BORING INC. OF DERRY, NEW HAMPSHIRE BETWEEN NOVEMBER 6 AND NOVEMBER 22, 2000

4.) TEST PITS AND TEST BORINGS WERE MONITORED BY A CDM REPRESENTATIVE AND WERE LOCATED BY FIELD SURVEY.

5.) ELEVATIONS ARE IN FEET AND REFER TO NATIONAL GEODETIC VERTICAL DATUM (NGVD) 1929.

6.) HORIZONTAL DATUM REFERS TO NORTH AMERICA DATUM (NAD) '83(1996) AS REFEREED TO THE RHODE ISLAND STATE PLANE COORDINATE SYSTEM

Subject: Preliminary Cost Estimate Report
T.F. Green Airport
Former Truck Away Landfill Site
Warwick, Rhode Island

Dear Laurie:

On Behalf of the Rhode Island Airport Corporation (RIAC), Camp Dresser & McKee, Inc. (CDM) hereby submits the enclosed Preliminary Cost Estimate Report for the former Truk Away Landfill Site at the T.F. Green Airport in Warwick, Rhode Island. As Agreed between RIAC, RIDEM and CDM, the goal of this evaluation was to obtain a preliminary, planning level cost estimate for three different site closure/improvement options for the site. An additional goal of this evaluation was to better estimate the degree of differential settlement between proposed site cargo building and associated ramps and taxiways. Our findings are enclosed in the attached report.

The estimate cost associated with the closure of the landfill and construction of cargo buildings makes this site improvement option economically infeasible. In addition, the expected long term differential settlement that would be experienced at the site is not within operational tolerances normally associated with aircraft travel over pavement. As part of the Master Plan/Environmental impact Study (EIS), (RIAC) is evaluating other potential site uses that will also incorporate measures to mitigate potential impacts to human health and the environment.

Please call either of the undersigned at (617) 452-6000 if you have any questions or if you need additional information.

Very truly yours,

Matthew Dentch, P.E.

Executive Summary

This Preliminary Cost Estimate Report for the former Truk Away Landfill (the site) at T. F. Green Airport in Warwick, Rhode Island has been prepared by Camp Dresser & McKee, Inc. (CDM) to provide a preliminary cost estimate for three site closure/improvement alternatives. These three alternatives were selected in consultation with RIAC to better define the long-term strategy for the site based on:

- The likelihood that each alternative would meet with approval from local, state and federal officials,
- The economic feasibility of each alternative,
- Regulatory requirements for landfill closure and
- Future airport operational needs.

The three alternatives do not provide a similar final site use, but instead were selected to provide RIAC with a conceptual design and preliminary cost estimate to evaluate the feasibility of site closure/improvement from an economic, regulatory and technical practicability standpoint. The three alternatives that were evaluated are as follows:

- Alternative 1 - Landfill closure as required by the Rhode Island Department of Environmental Management (RIDEM) regulations with no site improvements. Major landfill closure elements include a final cover system, perimeter storm water controls, gas collection and treatment (if required) and leachate collection and treatment (if required).
- Alternative 2 - Partial landfill closure to the west and southwest and implementation of a soil preloading program lasting up to 24 months to assist in mitigating long term settlement of the proposed ramps and taxiways. This alternative assumes that complete closure of the landfill would proceed after this alternative has been implemented as described in Alternative 1 or 3.
- Alternative 3 - Landfill closure as required by RIDEM regulations and the construction of four 30,000 square foot cargo buildings, ramps, taxiways and parking and a taxiway wetland crossing from Runway 16/34.

Prior to conducting the evaluation of the three alternatives, CDM undertook an initial environmental and geotechnical study of the site to further evaluate the engineering properties of the subsurface soils. Also, an evaluation of impacts to the adjacent wetlands from site closure/improvements and the state and federal environmental permits that will be required for these site closure/improvement options is presented. Lastly, CDM designed project site improvements to Federal Aviation Administration (FAA) design requirements.

Site Description and History

The former Truk Away Landfill is located within the southern portion of T.F. Green Airport in Warwick, Rhode Island. The landfill covers approximately 34 acres and is bounded to the west and northwest by industrial property, to the north by the southern end of Runway 34-16, to the east by the wetlands at the end of the runway and a former City of Warwick solid waste facility, and to the south by residential property. The landfill surface is vegetated with low growing shrubs and grasses and occasional stands of small trees with a maximum height of about 20 feet. Correspondence from Truk Away and Sanitas Waste Disposal to the Division of Solid Waste Management during the 1970's that have been made available to CDM suggests that extensive deposits of peat underlie the site. The waste materials placed in the landfill are not well documented but reference is made to "rubbish and construction demolition debris."

Summary of Previous Environmental and Geotechnical Investigations

Between October 19, and December 13, 2000, CDM undertook a limited environmental site investigation. Key findings of CDM's initial investigation included:

- The landfill's edge of waste generally corresponded to the site's fence line/property line to the south and west and with the edge of wetlands to the north and east.

- Soil and groundwater laboratory analysis results and field screening of soil vapor indicates that subsurface conditions at the site are typical of what would be expected at a landfill containing residential/commercial waste and construction demolition debris. Floating product, however, was detected at a thickness of about 2 feet in MW-3, which is located in the center of the landfill.

- Elevated concentrations of methane were reported in a number of vapor probes although the observance of elevated methane concentrations was restricted to the subsurface environment and not ambient, breathing zone areas.

The investigation described in CDM's Limited Site Investigation Report was intended as an initial investigation of subsurface conditions at the site and was not meant to include a comprehensive site investigation of the landfill area. More comprehensive investigations will likely be required to provide adequate information for landfill closure. If RIAC chooses not to pursue cargo building construction at the landfill, responsibility for further landfill investigations and closure will revert back to the Rhode Island Department of Transportation (RIDOT).

A report entitled Preliminary Subsurface Investigation and Geotechnical Feasibility Study by CDM and dated January 19, 2001 identified that significant settlement would likely occur with site improvements, namely the construction of air cargo buildings, ramps and taxiways. The anticipated settlement is a function of the existence of waste material and peat underlying the site. While short-term settlement can be mitigated through a pre-construction program involving deep dynamic compaction and/or soil preloading, the site would be expected to experience long-term settlement. The report concluded that long-term settlement of the buildings could be addressed by the installation of deep foundations; however, differential settlement between the buildings and airplane taxiways/building ramps would likely require long term maintenance over the life of the buildings, taxiway and ramps.

Alternative Evaluation Summary

The results of the alternative evaluation are summarized on Table ES-1. A review of this table identifies the following significant findings:

1. The preliminary estimated cost to implement landfill closure/cargo building construction (Alternative 3) is $46,100,000 including long-term operation and maintenance costs. This estimate takes into account escalation costs (4 percent per year) since the soil preloading program would extend construction duration to an estimated three year period. Advantages of this option include protection of human health and the environment through landfill closure, and creation of employment opportunities for the community. Disadvantages of this alternative include the high cost to implement and the uncertainty in obtaining regulatory approval for the proposed wetland crossing.

2. Although CDM has assumed a certain cost associated with addressing difference in settlement between buildings and ramps (as part of Alternative 3), operational issues associated with maintaining the proposed ramps are difficult to predict. While we believe that deep dynamic compaction, soil preloading and deep foundations will address short term settlement, the uncertainty of controlling a 12 inch difference in settlement over a 30 year design life requires significant attention by RIAC.

3. In all alternatives, regrading the landfill for closure purposes may attract a large bird population, which could pose a significant safety hazard to aircraft using the adjacent runway.

4. Significant wetland issues will be encountered in all three alternatives. In general, the wetlands at and adjacent to the former Truk Away Landfill are in a compromised state due to the highly developed nature of the airport and surrounding urban community. RIDEM and the United State Army Corps of Engineers, however, will still require RIAC or RIDOT to complete the necessary permitting activities associated with work in a wetland. Given these potential wetland impacts, it is likely that a compensatory wetland construction program

will be required within Warwick city limits to offset the wetland impacts from the proposed cargo building project.

To further complicate the wetland issues, a site improvement project north of the site on airport property is currently under development where a wetland crossing will be required. RIAC should consider the permitting sequence of the two projects and may want to consider permitting these projects together.

TABLE ES-1

ALTERNATIVE EVALUATION SUMMARY
FORMER TRUK-AWAY LANDFILL

T.F. GREEN AIRPORT
WARWICK, RHODE ISLAND

Alternative Description	Ability to Receive Regulatory Approval	Advantages	Disadvantages	Preliminary Estimated Cost
Alternative 1 - Landfill Closure	High	Protective of human health and the environment.	Doesn't address long-term airport needs. No increase in jobs for community Regrading may cause bird hazard.	$10,900,000
Alternative 2 - Partial Landfill Closure with Soil Preloading Program	Medium to High	Partially protective of human health and the environment. Allows RIAC more time to evaluate economic feasibility of proposed site future use.	Partial landfill closure technically more difficult than complete closure. Soil pre-loading piles require maintenance. Regrading may cause bird hazard. Partial closure would be complicated by financial responsibility between RIAC, RIDOA, and RIDOT.	$13,300,000
Alternative 3 - Landfill Closure with Cargo Building Construction	Medium	Protective of human health and the environment. Generates new jobs for community. Addresses long-term airport operational needs given lack of available real estate.	Regulatory approval for wetland crossing may be difficult. Local opposition may be high. Regrading may cause bird hazard. Difference in predicted settlement between buildings and ramps will require maintenance. High cost - payback evaluation required.	$46,100,000

Section 1
Introduction

This Preliminary Cost Estimate Report for the former Truk Away Landfill (the site) at T. F. Green Airport in Warwick, Rhode Island has been prepared by Camp Dresser & McKee, Inc. (CDM) to provide a preliminary cost estimate for three site closure/improvement alternatives. These three alternatives were selected in consultation with RIAC to better define the long-term strategy for the site. CDM has prepared a conceptual design challenges and preliminary cost estimate of the following three site closure/improvement options:

- Alternative 1 - Landfill closure as required by the Rhode Island Department of Environmental Management (RIDEM) with no site improvements.
- Alternative 2 - Partial landfill closure and implementation of a soil preloading program.
- Alternative 3 - Landfill closure and cargo buildings construction.

During 2000, CDM conducted a limited environmental site investigation and preliminary geotechnical engineering evaluation of the site to obtain the initial data to support this preliminary cost estimate. Prior to conducting the evaluation of the three alternatives, CDM undertook an additional geotechnical study of the site to further evaluate the engineering properties of the subsurface soils. The results of the recent geotechnical evaluation are presented in Section 2. Also, an evaluation of the adjacent wetlands and the state and federal environmental permits that will be required for these site closure/improvement options is presented. Lastly, CDM designed the proposed project site improvements to meet Federal Aviation Administration (FAA) requirements.

1.1 Site Description and History

The former Truk Away Landfill is located within the southern portion of T.F. Green Airport in Warwick, Rhode Island. The landfill covers approximately 34 acres and is bounded to the west and northwest by industrial property, to the north by the southern end of Runway 34-16, to the east by the wetlands at the end of the runway and a former City of Warwick solid waste facility, and to the south by residential property. The landfill surface is vegetated with low growing shrubs and grasses and occasional stands of small trees with maximum height of about 20 feet. Numerous piles and small areas of solid waste are located throughout the landfill, although no drums or containers that may store hazardous waste were noted on the ground surface during CDM's field investigations or site visits. A Locus Map is provided on **Figure 1-1** and a Site Plan is provided on **Figure 1-2**, contained in the report back pocket.

Figure 1-1
Site Locus

Correspondence from Truk-Away and Sanitas Waste Disposal to the Division of Solid Waste Management during the 1970's that have been made available to CDM suggests that extensive deposits of peat underlie the site. The waste materials placed in the landfill are not well documented but reference is made to "rubbish and construction demolition debris." The removal of batteries from the landfill has been reported to occur in the past.

1.2 Summary of Previous Environmental Investigations

Between October 19, and December 13, 2000, CDM undertook a limited environmental site investigation. Field activities conducted as part of this limited subsurface investigation included:

- Excavation of test pits around the landfill perimeter to delineate the edge of waste;
- Wetland flagging;
- Advancement of soil borings, including the collection and laboratory analysis of soil samples
- Installation of six monitoring wells;
- Monitoring well development
- Groundwater sampling and laboratory analysis; and
- Soil vapor monitoring.

Key findings of CDM's initial investigation included:

- The landfill's edge of waste generally corresponded to the site's fence line/property line to the south and west and with the edge of wetlands to the north and east.
- Soil and groundwater laboratory analysis results and field screening of soil vapor indicates that subsurface conditions at the site are typical of what would be expected at a landfill containing residential and/or commercial waste. The only compound detected in soil above RIDEM Industrial/Commercial Direct Exposure or Leachability Criteria was arsenic at two locations. The concentrations of arsenic detected (9.1 mg/kg and 6.8 mg/kg) could in fact be attributable to background conditions and are within the range of a typical urban fill area. The only compounds detected in groundwater samples at or above RIDEM GB Groundwater Objectives were toluene at 1.7 mg/l in MW-3 and ethylbenzene at 2.5 mg/l in MW-3 and 2.1 mg/l in MW-8. Floating product, however, was detected at a thickness of about 2 feet in MW-3, which is located in the center of the landfill.

- Elevated methane concentrations were reported in a number of vapor probes although the observance of elevated methane concentrations were restricted to the subsurface environment and not ambient, breathing zone areas. CDM anticipates that RIDEM will require closure of the landfill according to applicable RIDEM solid waste regulations, which require controls for methane.

The investigation described in CDM's Limited Site Investigation Report was intended as an initial investigation of subsurface conditions at the site and was not meant to include a comprehensive site investigation of the landfill area. More comprehensive investigations will likely be required to provide adequate information for landfill closure. In a letter dated June 22, 2001, RIDEM indicated that the following activities should be conducted prior to closure design:

- Delineation of the spatial extent of free product at the site;
- Determination of the volume of waste located beyond the southern site boundary;
- Bedrock groundwater investigations to evaluate whether dense non-aqueous phase liquids exist;
- More extensive landfill gas investigations; and
- Surface water and sediment sampling of the wetlands surrounding the site.

As part of the preliminary cost estimate, CDM has included the cost associated with additional environmental investigations at the site prior to closure. If RIAC chooses not to pursue cargo building construction at the landfill, responsibility for further landfill investigations and closure will revert back to Rhode Island Department of Transportation (RIDOT).

1.3 Summary of Previous Geotechnical Investigations

Preliminary cost estimates associated with soil preloading, deep dynamic compaction and deep foundation systems were presented in CDM's Preliminary Subsurface Investigation and Geotechnical Feasibility Study dated January 19, 2001. The results of the preliminary geotechnical investigation and feasibility evaluation identified that significant settlement would likely occur with site improvements, namely the construction of air cargo buildings, ramps and taxiways.

The anticipated settlement is a function of the existence of waste material and peat underlying the site. While short-term settlement can be mitigated through a pre-construction program involving deep dynamic compaction and/or soil preloading, the site would be expected to experience long-term settlement. The report concluded that long-term settlement of the buildings could be addressed by the installation of deep foundations; however, difference in settlement between the buildings and

taxiways/building ramps would likely require corrective action over the life of the buildings. RIAC and CDM agreed that additional geotechnical evaluations were warranted to support a preliminary cost estimate of proposed site improvement options and to better estimate long-term settlement. The results of these additional geotechnical evaluations are presented in Section 2.2 and their impacts to design of the three alternatives is presented in Section 3.

Section 2
Supplemental Geotechnical Engineering and Wetland Evaluations

This section presents the results of the geotechnical and wetland evaluations that were conducted during April and May 2001 as part of the evaluation of the three site closure/improvement options for the former Truk Away Landfill. Impacts that the geotechnical properties of site soils/waste material will have on the design of closure/improvement alternatives and the wetland permits required are discussed in Section 3 under each alternative.

2.1 Additional Geotechnical Evaluations

The purpose of the additional geotechnical evaluations undertaken as part of this study was to further investigate the subsurface conditions at the landfill. Specifically, the scope of work included the following:

- Advancing three (3) test borings within the limits of the landfill to further investigate subsurface conditions and obtain soil and waste samples for geotechnical laboratory testing;
- Conducting geotechnical laboratory tests to assist with classification and estimating engineering properties of the soil and waste encountered;
- Providing geotechnical engineering recommendations for foundation system alternatives and ground improvement techniques based on the additional subsurface information collected;

2.1.1 Subsurface Exploration Program

Three test borings (B-1 through B-3) were drilled as part of this evaluation to further investigate the subsurface conditions at the site. The test borings were drilled by New Hampshire Boring Inc. of Derry, New Hampshire between April 30 and May 2, 2001. The test borings were drilled using an all-terrain vehicle (ATV) drill rig. Test boring depths ranged from 22 feet to 47 feet below the existing ground surface. Split-spoon sampling was conducted at about five-foot intervals at each boring location in accordance with ASTM D1586. Representative samples were taken from each split-spoon collected in the waste and the underlying peat and naturally deposited sand and stored in jars for later review and laboratory testing.

A CDM representative observed the test borings in the field. Test borings were located in the field by taping from existing site features. Elevations were estimated relative to available site topography. Logs of the test borings, prepared by New Hampshire Boring and reviewed by CDM, are included in Appendix A. Figure 1-2 shows the approximate locations of the explorations. Test borings were backfilled with bentonite grout to an elevation approximately 5 feet above the bottom of the

waste material. The remainder of the test borings were backfilled with waste and spoil material. No monitoring wells were installed as part of this investigation.

2.1.2 Subsurface Conditions

Subsurface soil conditions were interpreted from the test borings conducted at the site and our understanding of the landfill history and local geology. A summary of subsurface conditions encountered during the first phase of test borings can be found in CDM's Preliminary Subsurface Investigation and Geotechnical Feasibility Study dated January 19, 2001. Test borings drilled within the landfill typically encountered cover soil and waste overlying naturally deposited peat, sand and gravel. Landfill cover material, consisting of medium dense to dense, brown to black, fine to medium sand with varying amounts of silt and gravel, was encountered in all of the recent borings. Cover thickness ranged from 1.5 to 2 feet with Standard Penetration Test (SPT) N-values ranging from 13 to 33 blows per foot (bl/ft). Waste was encountered in all three test borings. Waste material typically consisted of loose to dense black wood, paper, glass, cloth, soil, metal, wire and plastic. Waste thickness ranged from greater than 20.5 feet to 40.5 feet with SPT N-values ranging from 8 to 41 bl/ft.

In test borings B-1 and B-2, the lower 5 to 13 feet of the waste was mixed with the underlying peat soils. Samples taken within this zone consisted of very loose to medium dense black PEAT with varying amounts of waste material, silt, and sand. Typical SPT N-values in the peat and waste mix ranged from weight of hammer (WOH) to 11 bl/ft. The natural inorganic soils below the waste and peat mix were encountered in test borings B-1 and B-2. These soils typically consisted of loose to dense, gray, fine to coarse sand and gravel. Test boring B-2 encountered three feet of very loose, gray silt, trace roots overlying loose gray fine sand, little silt. Typical SPT N-values in the inorganic layer ranged from 8 bl/ft to 19 bl/ft and was encountered up to 7 feet in thickness. Test borings B-1 and B-2 were terminated in the naturally deposited inorganic sand and gravel stratum. Test boring B-3 was terminated within the waste. **Table 2-1** presents a summary of the recent subsurface explorations

2.1.3 Groundwater Levels

Groundwater levels in each test boring were estimated based on the conditions of the samples obtained and by the observed water levels within the borehole at the time of drilling. Groundwater was observed in test boring B-1 and was at approximately 16 feet below ground surface. Groundwater was not encountered in test borings B-2 and B-3.

Based on the groundwater encountered during drilling and measured in the existing monitoring wells, the original configuration of the site, and the surrounding wetlands, it appears that there may be pockets of water perched within the landfill waste material and the natural groundwater level is at approximately the top of the peat strata (between 20 and 40 feet below grade). Water levels measured in the explorations should not necessarily be considered to represent stabilized groundwater

levels. In addition, water levels are expected to fluctuate with season, temperature, climate, construction in the area, and other factors.

2.1.4 Laboratory Testing

Geotechnical laboratory tests were performed on selected waste and peat samples collected as part of this study to determine organic content, water content, plasticity and consolidation properties of these materials. In addition, more complete detailed visual classifications of the waste materials were obtained, which included descriptions of the type and percentage of materials comprising the waste.

Organic content (ASTM D2974) tests were performed on select waste samples recovered from all of the test borings. The results of organic content tests performed on waste samples ranged from 5.9% to 94.1%. Visual classifications of the waste samples indicated that the waste is comprised of several materials including; soil, plastic, paper, organics (wood, roots, etc.), and metal. Two undisturbed samples of the peat deposit were collected in test boring B-2. These peat samples, collected between 28 - 30 feet and 31 - 33 feet below ground surface, were also mixed with waste. The results of organic content tests performed on these samples ranged from 21.4% to 89.4% and, based on the Atterberg limits testing, are classified as OH (organic clays of medium to high plasticity, organic silts) or MH (inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts).

Consolidation tests (ASTM D2435) were performed on the undisturbed tube samples of peat collected from B-2. Consolidation tests were conducted to assist with settlement analysis. Based on the results of the consolidation tests, the peat can be considered normally consolidated and has a relatively high compressibility. The results of the laboratory tests are included in Appendix B.

The impacts that the site subsurface materials (peat and waste material) have on construction of the three alternatives and preliminary geotechnical design recommendations are presented in Section 3 under each alternative.

2.2 Wetland Issues

2.2.1 Additional Waste Delineation

To confirm the limits of waste delineation along the northern and eastern boundaries of the landfill, TMC Services, Inc. of Bellingham, Massachusetts excavated six test pits at locations along this area of the landfill. Previously, CDM had observed the excavation of 23 test pits around the perimeter of the landfill to delineate the edge of waste. Since proposed Alternative 3 will likely result in grading along this portion of the landfill, these additional test pits were conducted to verify the extent of waste in this area of the landfill.

Up to four test pits were excavated at each location until the approximate line of waste was encountered. Test pits were excavated on September 19, 2001 with a CAT 315B excavator. Test pit depths varied to up to 10 feet below ground surface. A CDM representative observed the test pit excavations in the field. The results of the test pit program identified that the approximate extent of waste along the northern and eastern side of the landfill is consistent with the results of the October 2000 test pit program. Edge of waste delineations is shown on Figure 1-2.

2.2.2 Wetland Evaluation

As part of the T. F. Green Airport Master Plan/Environmental Impact Statement work being conducted by Landrum and Brown (L&B), an evaluation of the wetland quality was undertaken. The wetlands on airport property were field-delineated by Applied Bio-Systems in the fall and winter of 2000-2001, per United States Army Corps of Engineers (USACE) and Rhode Island definitions. The delineation was field-surveyed and overlaid onto project topographic mapping. In general, the wetlands at and adjacent to the former Truk Away Landfill are in a compromised state due to the highly developed nature of the airport and surrounding urban community.

The wetlands on the airport are located along the eastern and southeastern perimeters of the airport property, as shown on Figure 2-2. All of these wetlands are fresh water wetlands and have no tidal influence. Most of these wetlands are associated with drainage channels or streams that flow off-airport to the east, south, and southeast, such that they are part of larger systems. Systems A, B, C include wetlands both on and off airport, while System D is located entirely within airport property. Systems C and D border the Truk-Away Landfill

System C

System C is comprised of perennial streams with forested borders and an open wetland of mostly common reed grass. It is located west and south of Runway 34 and east of Runway 5 receiving surface drainage from these areas. Wetlands in this system drain toward the end of Runway 34, where a culvert flows into Buckeye Brook. System C has three distinct areas. One wetland is located off-airport property, while the other two sections of the wetland are located within the airport boundary.

The primary channel of System C begins some 600 feet from the intersection of Runways 5 and 34, near the Airport Traffic Control Tower. Drainage from the airport is the origin of this perennial stream that flows in a southeast direction along the west side of Runway 34 and into Buckeye Brook. This wetland appears to have been significantly altered. Not only does piped drainage play a major role in its water regime, the land on its north and eastern edges has been built up by fill to form a steep 10-12 foot embankment that is regularly mowed.

Unlike the meandering and sometimes braided stream channel from the Industrial area that flows into it, some sections of the main channel have been straightened, with the channel bank along the airport property line as high as four feet. This stream, at

times orange in color, flows through a narrow forested area with red maple, black cherry, gray birch, oaks, willow, and black locust but no obviously dominant tree species. East of the forested area this section of wetland System C has a diverse but thin shrub growth of European buckthorn, steeplebush (Spirea tomentosa), northern bayberry (Myrica pensylvanica), high-bush blueberry, grapevines and poison sumac. Emergent plants include common reed grass, common cattails, purple loosestrife, tussock sedge, and moss. The area is wet but not saturated.

As the channel flows in a southeast direction approaching the end of Runway 34 the forested area turns into a thin edge of speckled alder (Alnus incana) trees, smooth sumac (Rhus glabra), open water and a common reed grass field. This portion of System C has a distinctly different character, as it is broad and open, more field than forest. The primary functions of this wetland are: floodflow alteration; sediment and toxicant retention; nutrient removal and retention; and wildlife habitat.

System D

System D is approximately 7.5-acres, dominated by common reed grass. It is located entirely within, and bordered on three sides by, the airport property perimeter. It is north of a Strawberry Field Road residential area, northwest of a former landfill, and east of Industrial Avenue. The edge closest the residential area is dominated by sweet pepperbush in the shrub layer and slopes down to the wetland's lowest point where skunk cabbage and common cattails are co-dominant in the herbaceous layer. As the wetland slopes to the north the elevation gradually rises. Here there is some purple loosestrife but common reed grass predominates. The wetland rises up to a prominent ridge that is mostly bare except for a few large trees.

The primary value of this wetland is nutrient removal because of its position downstream of a densely developed residential and industrial area. The extensive root system of the common reed grass and somewhat flat topography provide excellent opportunity for sediment/toxicant retention and nutrient uptake.

Wetland Systems Occurring On T. F. Green Airport

Figure 2-1

Section 3
Evaluation of Site Closure/Improvement Alternative

This section presents an evaluation of the three site closure/improvement options for the former Truk Away Landfill. Each alternative is described in the sections provided below, followed by an estimated cost for the alternative and discussions relative to geotechnical and wetland issues.

3.1 Overview of Site Closure/Improvement Alternatives

As presented in Section 1, three site closure/improvement alternatives were evaluated as part of this preliminary cost estimate. The three alternatives were selected with input from RIAC planning officials based on:

- the likelihood that each alternative would meet with approval from local, state and federal officials,
- the economic feasibility of each alternative,
- regulatory requirements for landfill closure and
- future airport operational needs.

The three alternatives do not provide a similar final site use, but instead were selected to provide RIAC with a conceptual design and the preliminary cost estimate to evaluate the feasibility of site closure/improvement from an economic, regulatory and technical practicability standpoint. The three alternatives that were evaluated are as follows:

- Alternative 1 - Landfill closure as required by RIDEM regulations with no site improvements. Major landfill closure elements include a final cover system, perimeter storm water controls, gas collection and treatment (if required) and leachate collection and treatment (if required).
- Alternative 2 - Partial landfill closure to the west and southwest and implementation of a soil preloading program lasting up to 24 months to further evaluate whether this option will mitigate long term settlement of the proposed ramps and taxiways.
- Alternative 3 - Landfill closure as required by RIDEM regulations and the construction of four 30,000 square foot cargo buildings, ramps, taxiways and parking and a taxiway wetland crossing from Runway 16/34.

It is important to note that the level of detail associated with the conceptual design provided herein will correlate with the level of detail required to prepare a

preliminary cost estimate for the three alternative described above. CDM has focused on design elements that can have the greatest impact on construction cost such as cut/fill volumes, landfill closure elements, building, taxiway and ramp construction and geotechnical support of buildings, ramps and taxiways. For construction cost items that are not specifically related to environmental or geotechnical issues, CDM used unit costs from recent construction projects or readily available unit cost publications. Detailed engineering cost estimates should be developed during preliminary and final design depending on which alternative is deemed feasible.

3.2 Alternative 1 – Landfill Closure

This alternative involves installing a landfill cover at the former Truk-Away landfill and construction of other landfill closure elements as required by RIDEM to mitigate potential impacts to human health or the environment.

3.2.1 Conceptual Design

Since filling activities have been reported as recently as 1995, it is highly likely that a final landfill cover will be required as part of site closure/development. Landfill closure components would include: a final cover, a combined active/passive landfill gas venting system, perimeter drainage and possibly a leachate/groundwater collection and treatment system.

This section describes the conceptual design of the landfill closure alternative for the project site. The landfill closure design is based upon the existing site topography and Rhode Island DEM Solid Waste Regulation No. 2 – Landfills dated January 1997.

The intent of the design is to minimize the re-handling of the waste to reduce the cost to implement this alternative and to minimize the potential bird hazard. With the exception of a few mounded hills within the landfill area, the terrain is well suited for landfill closure. The plateau is gently sloped at roughly a 2 percent grade and the side slopes leading from the edge of waste to the abrupt change in slope at the plateau are approximately 6(H): 1(V). The landfill cap is designed to contain the waste landfilled at the site and protect the environment and public health. The waste along the edge of the project will likely be pulled back somewhat to provide a clean surface from where to start the capping components.

The landfill capping requirements specified by RIDEM have the following goals. Final cover system is designed to minimize the infiltration of precipitation into the landfill and promote drainage from the surface while minimizing erosion and maintenance. The Final cover system that meets the above goals is as follows;

- 12-in. (min.) Topsoil layer (suitable for supporting Vegetation)
- Granular or synthetic filter fabric (to prevent clogging of the drainage layer)
- 12-in. (min.) Drainage layer
- Low Permeability layer (consisting of clay or HDPE liner)
- Bedding material (6-in. minimum layer thickness)

Side slopes include the following;

- Side slopes 3(H): 1(V)
- Slope at top of landfill (3-5%)
- Drainage layer must have slope of 5% to allow for subsidence

In addition to the above requirements, a leachate collection system, surface water controls, and a gas collection and treatment system will be included within the design. These elements are intended to collect and treat leachate from the landfilled waste, promote positive drainage flow from the landfill, and collect and treat landfill gases generated by the decomposition of the waste

The irregularly shaped and areas of varied topography of the existing site will need to be reshaped in some areas to provide a uniform surface for placement of capping components. This effort will have to be compared with the placement of imported fill from an economic perspective to minimize costs and construction time. The top plateau must be graded at a minimum slope of 5% to promote drainage flow. Presently, the top portion of the existing landfill is sloped at 2%, so material must be reshaped from existing cover materials, or imported from off-site to make up the difference. An economical source could be construction and debris material where generators will pay the disposal facility to accept the material. This would prevent rehandling of the present material and eliminate any costs related to the import of material to obtain desired sub grade levels. Given the uncertainty associated with state acceptance of this approach, our cost estimate assumed that landfill regrading and fill (soil) will be used to shape the landfill.

3.2.2 Estimated Cost

Capital cost for this alternative include: pre-closure environmental investigations, engineering design and permitting of the closure system, construction cost for the closure system (cut/fill for grading, surface water controls, landfill gas controls, the final cover, and leachate/groundwater controls), bird control costs, construction oversight, and air monitoring during construction. Other capital costs include non-construction items such as legal fees, contractor overhead and profit, and contingencies.

Operation and maintenance costs associated with this alternative include landfill cover maintenance, monitoring of the landfill gas control and leachate systems, and groundwater and surface water monitoring. To estimate the cost of this alternative, CDM has assumed that a leachate/groundwater collection and treatment system would operate for a five year period. CDM assumed this duration since it is unclear whether leachate collection and treatment will even be required. By assuming that a leachate collection and treatment will be required for a five year period to provide a conservative approach to cost estimating without assuming a more conservative 30 year leachate system operational period.

The present worth cost associated with this alternative is estimated to be $10,900,000 using a 30-year operation period and 4 percent interest rate. A table summarizing the cost of this alternative is presented in **Table 3-1**.

3.2.3 Preliminary Geotechnical Design Consideration

Relatively light loads will be associated with the landfill cover that will be added to the site as part of this option. CDM expects that the loads associated with construction of the cap will result in settlement of the underlying strata that is tolerable to the capping system. Therefore, no preloading or deep dynamic compaction of the landfill will be required for this alternative

3.2.4 Wetland Issues

This alternative would provide a beneficial outcome to the large wetland system to the east since the perimeter drainage and leachate/groundwater collection and treatment system would mitigate detrimental impacts from surface and groundwater. Although the smaller wetland systems that are located throughout the landfill would be filled in from landfill closure, these wetland systems have a low value due to the placement of solid waste.

Also, wetland permitting for this alternative would be streamlined since the landfill closure would likely be viewed as a remediation project. Generally when property owners conduct remediation projects where work is being conducted with the wetland resource are (or 50 foot buffer zone), the Waste Management and Wetlands sections of RIDEM discuss the project and issue an approval letter to conduct work in the wetland area.

3.3 Alternative 2 - Partial Landfill Closure and Soil Preloading

This alternative involves construction of a landfill closure system south of the proposed air cargo buildings (cargo building construction locations and description are described under Alternative 3), as well as, implementation of a soil pre-loading program in the area of the proposed cargo building ramps/taxiways. The purpose of this alternative is to protect human health and the environment through partial landfill closure. In addition, performing a preloading program to assist in mitigating long-term settlement and further evaluating whether this preloading program will allow RIAC to proceed with Alternative 3 in a cost-effective manner.

3.3.1 Conceptual Design

The proposed landfill closure elements south of the proposed cargo buildings represents placement of a landfill cover of approximately 9 acres. A description of the landfill closure elements is presented under Alternative 1. The rational behind this alternative is two-fold and includes the following:

* Used 4% interest rate for present worth analysis.

- By closing a portion of the landfill, the goal of protecting human health and the environment is partially addressed on an accelerated schedule;
- This alternative allows RIAC more time to evaluate the feasibility of air cargo construction while at the same time addressing potential long term differential settlement issues;
- Placement of the landfill cover in the areas of the proposed cargo buildings was not considered cost-effective due to difficult construction of deep foundations through a landfill cover system.

Soil preloading consists of temporarily placing excess fill in the area of future construction and over a compressible layer so as to cause consolidation settlement to occur prior to construction rather than after construction. In this alternative, CDM estimates that a 10 acre area located along the northeastern edge of the landfill will be the area subject to preloading. Once the layer has consolidated sufficiently, the excess fill is removed. The amount of excess fill required and duration of a preloading program are dependent on the type and thickness of material that is being preloaded as well as the foundation loading and tolerable settlement of the proposed permanent structures. Soil preloading is considered appropriate for portions of the site that are primarily underlain by peat soil rather than primarily waste material. The southern and eastern portion of the site appears to be primarily underlain by peat deposits of varying thicknesses.

3.3.2 Estimated Cost

Capital cost for this alternative include: pre-closure environmental investigations, engineering design of the closure system, construction cost for the closure system (cut/fill for grading, surface water controls, landfill gas controls, the final cover, and leachate/groundwater controls), construction oversight, air monitoring during construction, soil placement for pre-loading and installation and monitoring of settlement points. Other capital costs include non-construction items such as legal fees, contractor overhead and profit, permitting and contingencies. Operation and maintenance costs associated with this alternative include landfill cover maintenance, monitoring of the landfill gas control and leachate systems, and groundwater and surface water monitoring.

The present worth cost associated with this alternative is estimated to be $ 13,300,000 using a two year operation period and four percent interest rate. This alternative only addresses the execution of a soil preloading program and installation of a partial landfill closure system. A long-term operation and maintenance period was not included since this alternative would be the first phase of site closure/improvement scenario that could lead to continuing with Alternative 3. A table summarizing the cost of this alternative is presented in **Table 3-2**.

3.3.3 Preliminary Geotechnical Design Consideration

As discussed for Option 1, portions of the landfill which are closed with no further development (other than cars/trucks traffic) are expected to result in settlement of the underlying strata, due to the placement of the landfill cap and paving system that is tolerable to the capping system.

Based on the laboratory tests that were performed on samples of the peat encountered at the site, CDM estimates that a preload program consisting of 20 feet of excess fill placed over the area of the proposed site improvements would need to remain in place for up to 24 months. This excess fill is in addition to the 6 to 20 feet of fill that will be placed for grading purposes in this area. The required duration of the preload program could be reduced by increasing the amount of excess fill placed. After removal of the excess fill, the proposed site improvements are estimated to experience up to 6 inches of post-construction primary (consolidation) settlement.

Although a preload program will help limit post-construction consolidation settlement, long-term creep settlement will be lessened but not eliminated. Organic soils with a high organic content, such as peat, should be expected to experience significant long-term creep settlement. The amount of long-term settlement is dependent on the thickness and creep characteristics of the underlying material as well as time. Based on the laboratory testing that was performed on the peat samples, we estimate that the long-term creep settlement of the peat soils at the site will result in approximately 6 to 12 inches of additional settlement over approximately 30 years. The amount of long term creep settlement will be less in areas of thinner layers of underlying peat.

Construction considerations for the use of soil preloading as a means to improve the settlement characteristics of the peat deposit at the site include the following:

- Granular material suitable for use in a soil preload program is anticipated to be readily available;
- Placement of the preload material is anticipated to be accomplished with conventional earth moving equipment;
- Fill used as part of a preloading program should be placed in conjunction with site filling around the perimeter of the landfill and can be used as part of a final landfill cover; and
- Preloading will reduce the amount of long-term creep settlement, however, preloading is not expected to eliminate long-term creep settlement associated with decomposition of the peat soils. This additional settlement will need to be incorporated into the design of the proposed structures. In addition, long-term

creep settlement should be monitored and maintenance will likely be needed over time.

3.3.4 Wetland Issues

Alternative 2 involves preliminary activities (soil preloading and partial landfill closure) with the ultimate goal of constructing cargo buildings on the landfill. Impacts to wetlands from the soil preloading program will occur since the soil preloading will be conducted adjacent to the wetlands and in some cases with the wetland boundary. Since the RIDEM review period for a project of this magnitude can be up to 18 months, it would be prudent to submit a permit application to RIDEM that encompasses not only the soil preloading program but also the full landfill closure project and cargo building construction. Since the ultimate goal of Alternative 2 is the same as Alternative 3, the reader is referred to Section 3.4.4 for a description of potential wetland issues associated with Alternative 2.

3.4 Alternative 3 – Landfill Closure and Cargo Building Construction

This alternative involves installing a landfill cover at the former Truk-Away landfill and construction of other landfill closure elements as required by RIDEM to mitigate potential impacts to human health or the environment. In addition, this alternative involves construction of four 30,000 square foot cargo buildings, ramps, and taxiways, paved parking areas, site drainage and landscaped areas.

3.4.1 Conceptual Design

The conceptual design for this alternative includes the construction of a cargo terminal to be served by freight aircraft and large trucks. The Cargo Terminal consists of a total of 120,000 square feet of cargo space (in four–30, 000 square feet buildings) sited parallel to Runway 16/34. The aircraft access the proposed facility by the extension of a taxiway into the landfill site, and vehicular access is gained from an existing roadway, namely, Warwick Industrial Drive.

The specific design elements of this alternative is based upon geometric guidelines published by the US DOT and Federal Aviation Administration (FAA) Advisory Circular AC 150 - Airport Design Manual. For maximum flexibility and for aircraft accessibility standards, the preliminary design uses geometry for Aircraft Design Group IV (ADG IV) for aircraft up to and including the size of a Boeing 767-300. The Cargo Facility Preliminary Design shown on Figure 3-3 depicts the Preliminary Design described herein. Primary Surface Zones and limitations on the maximum gradient of taxi lanes govern the surface elevations within the approach to the cargo buildings. Alignment of the taxi lane is also driven by the convention that airport design requirements generally favors parallel or perpendicular geometry.

Implementation of this alternative will involve the following steps:

- Rehandling or relocation of existing waste and soil,
- Preloading and deep dynamic compaction of peat/waste material
- Following sufficient preloading, constructing a cap over the 34 acres landfill to RIDEM specifications (with the exception of topsoil layer in areas reserved for future construction),
- Construction of cargo facility including deep foundations and structural slabs for buildings

Soil preloading (as discussed under Alternative 2) in areas of minimal waste and thick peat layers and deep dynamic compaction (as described in Section 3.4.3) in areas of waste material is required to mitigate short and long term settlement of the taxiways and ramps.

Construction of a cap over the landfill to RIDEM specifications. This involves the following (from Option1):

- Granular or synthetic filter fabric (to prevent clogging of the drainage layer)
- 12-in. (min.) Drainage layer
- Low Permeability layer (consisting of clay or HDPE liner)
- Bedding material (6-in. minimum layer thickness)

In areas not intended for development, the above components are covered with a topsoil layer intended to support vegetative growth for stability and appearance.

Construction of the cargo facilities will involve deep foundations and/or structural slabs for the buildings. For cost estimating purposes, CDM assumed that the cargo buildings would be constructed of metal exterior with interior finishes suitable for use as a cargo storage facility. Concrete taxiway and aprons are proposed between the existing runway and the proposed buildings.

Implementation of this alternative includes the direct alteration of wetland areas in order to comply with horizontal geometry requirements set forth by the FAA. Some disturbance along the fringe of the wetland boundary will be necessary in any event in order to contain the waste. These impacts are discussed further in Section 3.4.4.

3.4.2 Estimated Cost

Capital cost for this alternative include: pre-closure environmental investigations, engineering design of the closure system, construction cost for the closure system (cut/fill for grading, surface water controls, landfill gas controls, the final cover, and leachate/groundwater controls), construction oversight, and air monitoring during

construction. Other capital costs include non-construction items such as legal fees, contractor overhead and profit, permitting and contingencies. Operation and maintenance costs associated with this alternative include landfill cover maintenance, monitoring of the landfill gas control and leachate systems, and groundwater and surface water monitoring. For cost estimating purposes, CDM assumed that the leachate/groundwater collection and treatment system would operate for a five year period, as discussed in Alternative 1.

The present worth cost associated with this alternative is estimated to be $ 46,100,000 using a 30 year operation period and 4 percent interest rate. The 30 year O&M period covers pavement maintenance and erosion control. Based on CDM's preliminary understanding of site conditions and RIDEM regulatory requirements, the following additional O&M periods were assumed: leachate collection/treatment (5years), groundwater and surface water monitoring and landfill gas treatment monitoring (10 years), and settlement plate monitoring for the soil preloading program (2 years). A table summarizing the cost of this alternative is presented in **Table 3-3**.

3.4.3 Preliminary Geotechnical Design Consideration

As stated in CDM's previous geotechnical report, the existing waste and peat soils underlying the site are not considered suitable for foundation support of the proposed taxiways, aprons, or structures. These strata are highly compressible and lack sufficient strength to adequately support the proposed site improvements without excessive post-construction settlement.

The recent subsurface investigation did not reveal information about the waste material that impacted our previous analysis but rather confirmed the assumptions we made as part of that study. The geotechnical laboratory testing results provided more technical evidence concerning estimated long-term settlement and allows CDM and RIAC a greater degree of confidence in estimating both long-term settlement and estimated costs for Alternative 3.

As discussed in our previous report, deep dynamic compaction (DDC) can be used to treat the in-place waste material and reduce settlement of the underlying material. We recommend that DDC be used in areas of ramps, taxiways, and parking that are underlain primarily by waste material. The cargo buildings will not likely be able to tolerate the long-term creep settlement associated with decomposition of the waste or peat and, as such, we recommend that the structures be supported on deep foundations bearing in the underlying sand and gravel stratum.

DDC is a ground improvement technique that consists of repeated tamping of the ground surface by dropping heavy steel or concrete weights. Typically the weights are about 6 to 20 tons and are dropped in a grid pattern by a crane from various heights depending on the amount of energy required. Dropping the weights produces shock waves that propagate through the underlying material that consolidates the material resulting in reduced void space, increased density and

* Used 4% interest rate for present worth analysis.

reduced long-term settlement of the underlying material. Larger weights and/or higher drop heights are required to treat thick deposits.

DDC is most effective on material that is above the water table and primarily granular in nature. The presence of groundwater and high fines content of the material tend to dampen the impact of DDC. DDC is not considered suitable for treatment of peat soils.

Once compacted, volume change of the underlying material of about 5 to 10 percent can be achieved for older landfills and up to about 25 percent for younger landfills. The increase in volume change for younger landfills, i.e., landfills which are still actively undergoing degradation, is thought to represent that portion of settlement that occurred previously in the older, now less active, landfills. The amount of volume change resulting from DDC is estimated by measuring how much the ground surface is lowered, i.e., crater depth. If insufficient volume change is initially achieved, repeated drops at one location may be required.

Lightweight structures constructed on top of DDC waste at other landfill sites have been reported to experience post construction settlement in the range of 0.25 percent of the underlying consolidated waste thickness (Ref. Lukas and Seiler, 1994). For purposes of this study, we estimate that the medium-weight to heavy-weight cargo facilities proposed at the site may experience up to approximately 12-in. of post construction primary settlement after DDC treatment. However, settlement estimates of DDC-treated waste should be made based on the characteristics of the site specific waste. Thus, a geotechnical subsurface investigation program is required after the DDC program is completed.

It should be noted that DDC-treated waste is still expected to experience some long-term creep settlement. The amount of creep settlement is dependent on the age of the waste and the amount of degradation that has occurred previously. For purposes of this study, we estimate that up to 1 foot of post construction long-term creep settlement may occur at the site after DDC treatment, although buildings constructed on deep foundations would not experience this amount of long-term settlement.

Deep foundations, consisting of driven or drilled-in piles, can be used to support the proposed cargo facilities. Supporting the taxiway and aprons on deep foundations is not considered cost effective. We recommend that other methods be used to limit post construction settlement of slabs-on-grade, taxiways, ramps and aprons. Deep foundations used to support buildings should extend through the waste and peat soils and bear in the underlying sand and gravel deposit. However, installing piles through the waste may be difficult due to the potential to encounter obstructions. Installation of drilled-in piles may accommodate obstructions somewhat better since the obstruction may be able to be removed using the drilling equipment.

Drilled-in piles should be designed to develop capacity as friction in the sand and gravel deposit with an allowable adhesion value of 500 pounds per square foot (psf).

Downdrag loads on the piles from ongoing settlement of the waste or peat should be considered in the design. Downdrag loads should be expected to be large. Settlement of structures supported on deep foundations is estimated to be less than one inch with no long-term creep settlement.

The lowest level floor slabs can be constructed as structural slabs that are supported on deep foundations. Alternatively, the slabs can be constructed as slabs-on-grade provided the slabs are separated from the portion of the building supported on deep foundations and can tolerate both primary and long-term settlement of the underlying waste and/or peat. Since settlement of slabs-on-grade, without DDC or preloading, are estimated to be excessive, we do not recommend that building slabs be supported on grade.

3.4.4 Wetland Issues

Constructing a taxiway from Runway 34-16 to the proposed cargo buildings will require a wetlands crossing at the site. Also the proposed taxiway on the eastern side of the landfill will require alterations to the wetlands in this area. Given these potential wetland impacts, it is likely that a compensatory wetland construction program will be required within Warwick city limits to off-set the wetland impacts from the proposed cargo building project. This section will discuss wetland impacts from the proposed project and wetland permitting issues related to this alternative.

This evaluation was prepared by Applied BioSystems of Kingston, Rhode Island and was prepared in accordance with the requirements of Section 10.03 and 11.02 of the Rules and Regulations Governing the Administration and Enforcement of the Freshwater Wetlands Act, April 1998. The wetland delineation at the landfill area was conducted on-site by Applied Bio-Systems, Inc. during September and October 2000.

The project will alter approximately 189,486 square feet of wetland area. This will be a direct loss of wetland area that is primarily associated with the intermittent stream channel. The three smaller wetlands that will be impacted are of lower wetland quality. These wetlands are contained in depressions and appear to have been created from past land use disturbances. The Area Subject to Flooding (ASF) was observed to contain water only following rainfall events. The wetlands are dominated with exotic and invasive plant species that have limited wildlife value. The plants observed include: common reed (Phragmites australis), purple loosestrife (Lythrum salicaria), Japanese bamboo (Polygonum cuspidatum). Sheet 60 of the Soil Survey of Rhode Island classifies these three small wetlands, as well as the entire land fill area, as having a Dumps (Du) soil unit. This soil unit consists of areas used for trash disposal (Rector, USDA, 1981). Although a large amount of permanent wetland alterations will result from this project; the wetland resources that will be disturbed are not functioning as healthy ecosystems.

A detailed evaluation of the review criteria that RIDEM – Office of Water Resources will review to determine whether this project represents a significant alteration of

wetlands is presented in Appendix C. A summary of the evaluation is provided below. The term project as stated below refers to the proposed Alternative 3.

Based on the evaluation of potential wetland impacts from Alternative 3, ABS highlighted the following significant findings:

- The project does not expect to significantly reduce the overall wildlife production of any of the wetland areas. Presently, the wetlands are in a compromised state due to the highly developed nature of the airport and surrounding urban community.

- It is not expected that there will be any significant reduction in the ability of the wetland area to satisfy the needs of a particular wildlife species. There are no wildlife species known to inhabit the wetlands on site whose requirements are so particular that they will not be satisfied as a result from the loss of wetland habitat. Also, there are no known rare wetland types, animal or plant species in the vicinity of the project.

- It is not expected that there will be a significant reduction in the suitability of any wetland for use by any wildlife species in the short-term or long-term. The intermittent stream channel will be altered which may reduce the suitability of the wetland for use as a travel corridor. Presently, the stream appears to be in a compromised water quality condition based on the red color and odors observed during the wetland delineation. Also, the airport is currently undertaking an odor control project within the stream near the control tower because of the odors produced by the de-icing chemicals that drain into the stream. It is unlikely that wetland-dependent wildlife species such as amphibians, turtles, otter, beaver, and mink would use this stream based on its present condition.

- It is not expected that there will be any more than a minimal intrusion of, or increase in, less valuable, invasive and/or exotic plant or animal species in a wetland due to the project.

- There are presently no opportunities for any passive or active recreational activities available to the public. There will be no elimination or severe limitation of any traditional human access to, along the bank of, up and/or down, or through any rivers, streams, ponds, or other freshwater wetlands. The entire airport property is completely restricted to the public for security purposes.

- The project does not expect to reduce the water quality functions and values or negative impacts to the natural water quality characteristics, either in the short- or long-term. Presently, the stream appears to be in a compromised water quality condition based on the red color and odors observed during the wetland delineation.

- There will be no placement of any matter or material beneath the surface water elevations or any erection of barriers within any ponds or flowing bodies of water that could cause any hazards to safety.

- There will be no restriction or significant modification of the path and/or velocities of flood flows for the 2-year, 10-year, 25-year, or 100-year frequency, 24-hour, Type III storm events so as to cause harm to life, property, or other functions and values provided by the freshwater wetland. There will be no placement of any structure or obstruction within a floodway so as to cause harm to life, property, or other functions and values provided by freshwater wetland.

There are three isolated wetlands within the project vicinity. All three of these wetlands will be permanently impacted by the project. The three smaller wetlands that will be impacted are of low wetland quality. These wetlands are contained in depressions and appear to have been created from past land use disturbances. The wetlands are dominated by exotic and invasive plant species that have limited wildlife value. Although a large amount of permanent wetland alterations will result from this project, the wetland resources that will be disturbed are not functioning as healthy ecosystems.

3.4.5 Permitting Required

RIDEM (Wetlands Division) will have jurisdiction over all the wetland areas within the project vicinity. A 50 foot Perimeter Wetland will be applied to the biological (flagged) edges of wetland. The other wetland areas are too small to receive a buffer. The intermittent stream channel will receive a 100 foot Riverbank Wetland extended from the riverbank edge as area within RIDEM jurisdiction. Any alterations proposed within these areas will need prior approval from RIDEM – Wetlands Division.

Also, this project will require an Application to Alter Freshwater Wetlands (formal application). The average review period for RIDEM – Wetlands is approximately twelve to eighteen months. This is dependent upon the application being complete and the wetland delineation being accurate with the wetland flagging visible in the field. An approval from RIDEM will require that the project minimize all impacts to freshwater wetlands and that there are no other alternatives. Several factors to consider may include the following:

- Are there any other areas within the airport property that this project could be constructed to avoid altering wetland areas;

- Can a detention system be designed to adequately handle the additional storm water flows from the project;

- Can the scale of this project be reduced; and
- If an additional, nearby development project is proposed, can both areas use the same access way.

The Army Corps of Engineers (ACOE) also has jurisdiction over all direct fill that is placed within wetland areas. Based on the large size of the alteration, greater than 1 acre in fill, this project would require an Individual Permit with the ACOE. Also, a RIDEM Water Quality Permit will be required.

3.5 Alternative Evaluation Summary

The results of the alternative evaluation are summarized on Table 3-1. A review of this table identifies the following significant findings:

1. The preliminary estimated cost to implement landfill closure/cargo building construction (Alternative 3) is $ 46,100,000 including long-term operation and maintenance costs. This estimate takes into account escalation costs (4 percent per year) since the soil preloading program would extend construction duration to an estimated three year period. Advantages of this option include protection of human health and the environment through landfill closure, and creation of employment opportunities for the community. Disadvantages of this alternative include the high cost to implement and the uncertainty in obtaining regulatory approval for the proposed wetland crossing.

2. Although CDM has assumed a certain cost associated with addressing differential settlement between buildings and ramps (as part of Alternative 3), operational issues associated with maintaining the proposed ramps are difficult to predict. While we believe that deep dynamic compaction, soil preloading and deep foundations will address short term settlement, the uncertainty of controlling a 12 inch difference in settlement over a 30 year design life requires significant attention by RIAC.

3. In all alternatives, regrading the landfill for closure purposes may attract a large bird population, which could pose a significant safety hazard to aircraft using the adjacent runway.

4. Significant wetland issues will be encountered in all three alternatives. In general, the wetlands at and adjacent to the former Truk Away Landfill are in a compromised state due to the highly developed nature of the airport and surrounding urban community. RIDEM and the United State Army Corps of Engineers, however, will still require RIAC or RIDOT complete the necessary permitting activities associated with work in a wetland. Given these potential wetland impacts, it is likely that a compensatory wetland construction program will be required within Warwick city limits to off-set the wetland impacts from the proposed cargo building project.

To further complicate the wetland issues, a site improvement project north of the site on airport property is currently under development where a wetland crossing will be required. RIAC should consider the permitting sequence of the two projects and may want to consider permitting these projects together.

TABLE 3-1

ALTERNATIVE EVALUATION SUMMARY
FORMER TRUK-AWAY LANDFILL

T.F. GREEN AIRPORT
WARWICK, RHODE ISLAND

Alternative Description	Ability to Receive Regulatory Approval	Advantages	Disadvantages	Preliminary Estimated Cost
Alternative 1 - Landfill Closure	High	Protective of human health and the environment.	Doesn't address long-term airport needs. No increase in jobs for community Regrading may cause bird hazard.	$10,900,000
Alternative 2 - Partial Landfill Closure with Soil Preloading Program	Medium to High	Partially protective of human health and the environment. Allows RIAC more time to evaluate economic feasibility of proposed site future use.	Partial landfill closure technically more difficult than complete closure. Soil pre-loading piles require maintenance. Regrading may cause bird hazard. Partial closure would be complicated by financial responsibility between RIAC, RIDOA, and RIDOT.	$13,300,000
Alternative 3 - Landfill Closure with Cargo Building Construction	Medium	Protective of human health and the environment. Generates new jobs for community. Addresses long-term airport operational needs given lack of available real estate.	Regulatory approval for wetland crossing may be difficult. Local opposition may be high. Regrading may cause bird hazard. Difference in predicted settlement between buildings and ramps will require maintenance. High cost - payback evaluation required.	$46,100,000

Appendix C
Evaluation of RIDEM Review Criteria – Wetland Alterations

Criteria Evaluation Against RIDEM Wetland Permitting

1) *Significant reduction in the overall wildlife production and/or diversity of a wetland*;

The project does not expect to significantly reduce the overall wildlife production of any of the wetland areas. Presently, the wetlands are in a compromised state due to the highly developed nature of the airport and surrounding urban community. It appears that a greater threat to wildlife will occur from the loss of the large open space that the landfill provides to wildlife species that use the area for nesting, hunting, and resting. This development will directly impact small mammal populations, coyote (*Canis latrans*), red fox (*Vulpes vulpes*), hunting hawks, and field species of birds.

2) *Significant reduction in the ability of a wetland to satisfy the needs of a particular wildlife species*;

No, it is not expected that there will be any significant reduction in the ability of the wetland area to satisfy the needs of a particular wildlife species. There are no wildlife species known to inhabit the wetlands on site whose requirements are so particular that they will not be satisfied as a result from the loss of wetland habitat.

3) *Significant displacement or extirpation of any wildlife species from a wetland or surrounding areas due to the alteration of the wetland*;

It is expected that there will not be a significant displacement or extirpation of any wildlife species from the wetlands or surrounding areas due to the project. It is expected that many of those wildlife species utilizing the habitat will remain in the surrounding area once the construction is complete.

4) *Any reduction in the ability of the wetland to ensure the long-term viability of any rare animal or rare plant species*;

There are no known rare animal or plant species in the vicinity of the project.

5) *Any degradation in the natural characteristic(s) of any rare wetland type*;

There are no rare wetland types present within the vicinity of the project area.

6) *Significant reduction in the suitability of any wetland for use by any resident, migratory, seasonal, transient, facultative, or obligate wildlife species, in either the short-term or long-term as a travel corridor; feeding site; resting site; nesting site; escape cover; seasonal breeding and/or spawning area*;

It is not expected that there will be a significant reduction in the suitability of any wetland for use by any wildlife species in the short-term or long-term. The intermittent stream channel will be altered which may reduce the suitability of the wetland for use as a travel corridor. Presently, the stream appears to be in a compromised water quality condition based on the red color and odors observed during the wetland delineation. Also, the

based on the red color and odors observed during the wetland delineation. Also, the airport is currently undertaking an odor control project within the stream near the control tower because of the odors produced by the de-icing chemicals that drain into the stream. It is unlikely that wetland-dependent wildlife species such as amphibians, turtles, otter, beaver, and mink would use this stream based on its present condition. The other wetland areas do not provide wildlife species with quality habitat. The shrub wetland and the Emergent Plant Community do provide species of wildlife with areas for feeding, resting, nesting, escape cover, and seasonal breeding.

7) *Any more than a minimal intrusion of, or increase in, less valuable, invasive and/or exotic plant or animal species in a wetland*;

It is not expected that there will be any more than a minimal intrusion of, or increase in, less valuable, invasive and/or exotic plant or animal species in a wetland.
The existing condition of the large swamp located within the property is dominated with common reed. Other invasive species noted within the wetland areas include purple loosestrife and Japanese knotweed. No invasive and/or exotic plant or animal species will be purposefully introduced into the project vicinity.

8) *Significant reduction in the wildlife habitat functions and values of any wetland which could disrupt the management program for any game or non-game wildlife species carried out by state or federal fish, game, or wildlife agencies*;

There will be no disruption to any management program carried out by state or federal fish, game, or any other wildlife agencies that will significantly reduce the wildlife habitat functions and values of any game or non-game wildlife species. Any game or non-game species that are managed by any wildlife agencies such as: white-tailed deer (*Odocoileus virginianus*), eastern cottontail (*Sylvilagus floridanus*), coyote, and red fox will need to relocate to other suitable areas. The more important habitat feature of the landfill area appears to be the large open upland habitat.

9) *Significant reduction in overall existing or potential ability of a wetland to provide active or passive recreational activities to the public*;

There are presently no opportunities for any passive or active recreational activities available to the public. The entire airport property is completely restricted to the public for security purposes.

10) *Significant disruption of any on-going scientific studies or observations*;

There are no known on-going scientific studies or observations that will be significantly disrupted from the proposed project.

11) *Elimination of, or severe limitation to traditional human access to, along the bank of, up and/or down, or through any rivers, streams, ponds, or other freshwater wetlands*;

There will be no elimination or severe limitation of any traditional human access to, along the bank of, up and/or down, or through any rivers, streams, ponds, or other freshwater wetlands. There are no traditional human access ways to any wetland area within the vicinity of the project. Again, the entire airport property is completely restricted to the public for security purposes.

12) *Any reduction in water quality functions and values or negative impacts to natural water quality characteristics, either in the short- or long-term, by modifying or changing: water elevations, temperature regimes, volumes, velocity of flow regimes or water; increasing turbidity; decreasing oxygen; causing any form of pollution; or modifying the amount of flow or nutrients so as to negatively impact wetland functions and values*;

The project does not expect to reduce the water quality functions and values or negative impacts to the natural water quality characteristics, either in the short- or long-term. The project does not expect to modify or change the volumes, velocity of flow regimes or water, decrease oxygen, cause any form of pollution, or modify the amount of flow or nutrients so as to negatively impact wetland function and values. Presently, the stream appears to be in a compromised water quality condition based on the red color and odors observed during the wetland delineation. Also, the airport is currently undergoing odor control project within the stream near the control tower because of the odors produced by the de-icing chemicals that drain into the stream.

13) *Any placement of any matter or material beneath surface water elevations or erection of any barriers within any ponds or flowing bodies of water which could cause any hazards to safety*;

There will be no placement of any matter or material beneath the surface water elevations or any erection of barriers within any ponds or flowing bodies of water that could cause any hazards to safety.

14) *Significant loss of important open space or significant modification of any uncommon geologic or archaeological features*;

There will be no significant loss of important open space or a significant modification of any uncommon geologic or archaeological features. The landfill area is a highly disturbed area and therefore there are no uncommon geologic or archaeological features.

15) *Significant modification to the natural characteristics of any wetland area of unusually high visual quality*;

There are no wetlands present within the airport property that provide an unusually high visual quality. These wetland systems are within the fenced private property of the airport and are situated within a highly disturbed setting.

16) *Any decrease in the flood storage capacity of any freshwater wetland which could impair the wetland's ability to protect life and/or property from flooding and/or flood flows*;

This project does not expect to decrease the flood storage capacity of the intermittent stream and Wooded Swamp. Any decrease in the capacity of the 100 year floodplain will be compensated by the development of flood basins.

17) *Significant reduction of the rate at which flood water is stored by any freshwater wetland during any flood event*;

There will be no significant reduction of the rate at which flood water is stored by any freshwater wetland during any flood event.

18) *Restriction or significant modification of the path and/or velocities of flood flows for the 2-year, 10-year, 25-year, or 100-year frequency, 24-hour, Type III storm events so as to cause harm to life, property, or other functions and values provided by freshwater wetlands*;

There will be no restriction or significant modification of the path and/or velocities of flood flows for the 2-year, 10-year, 25-year, or 100-year frequency, 24-hour, Type III storm events so as to cause harm to life, property, or other functions and values provided by the freshwater wetland.

19) *Placement of any structure or obstruction within a floodway so as to cause harm to life, property, or other functions and values provided by freshwater wetlands*;

There will be no placement of any structure or obstruction within a floodway so as to cause harm to life, property, or other functions and values provided by freshwater wetland.

20) *Any increase in run-off rates over pre-project levels or any increase in receiving water/wetlands peak flood elevations for the 2-year, 10-year, 25-year, or 100-year frequency, 24-hour, Type III storm events which could impair the wetland's ability to protect life and/or property from flooding and/or flood flows*;

There will be no increase in run-off rates over pre-project levels or any increase in receiving water/wetlands peak flood elevations for the 2-year, 10-year, 25-year, or 100-year frequency, 24-hour, Type III storm events which could impair the wetland's ability to protect life and/or property from flooding and/or flood flows.

21) *Any increase in run-off volumes and discharge rates which could, in any way, exacerbate flooding conditions in flood-prone areas*;

The project area does not appear to be a flood-prone area. There will be an increase in run-off volumes and discharge rates which could exacerbate flooding conditions in flood-

prone areas due to the proposed significant increase of impervious surface. This will be further clarified after design.

22) *Significant changes in the quantities and discharge rates of surface and/or groundwater to or from isolated wetlands (e.g., those wetlands without inlets or outlets);*

There are three isolated wetlands within the project vicinity. All three of these wetlands will be permanently impacted by the project. Wetland 1 and 5 will be permanently filled and Wetland 3 will be partially filled from the proposed project. The three smaller wetlands that will be impacted are of low wetland quality. These wetlands are contained in depressions and appear to have been created from past land use disturbances. The wetlands are dominated by exotic and invasive plant species that have limited wildlife value. Although a large amount of permanent wetland alterations will result from this project; the wetland resources that will be disturbed are not functioning as healthy ecosystems.

23) *Placement of any structural best management practices within wetlands, or proposal to utilize wetlands as a detention or retention facility;*

There will be placement of any structural best management practices within the wetland. However, the wetland will not be used as a detention or retention facility.

24) *Any more than a short-term decrease in surface water and/or groundwater elevations within any wetland;*

There will be no short-term decrease or any decrease in surface water and/or groundwater elevations within the wetland.

25) Non-compliance with the Rhode Island Department of Environmental Management Water Quality Regulations for Water Pollution Control; and/or

This project will require an approval from RIDEM – Water Quality Section.

26) Any detrimental modification of the wetland's ability to retain and/or remove nutrients or act as natural pollution filter.

This is not known at this stage in the design process.

RE: Truk-Away Landfill
Industrial Drive
Warwick, Rhode Island

Dear Mr. Walusiak:

Lincoln Environmental, Inc. gauged and sampled groundwater monitoring well MW-3 on December 8, 2004, wells MW-1, MW-5, MW-6, and MW-8 on December 30, 2004 and well MW-7 on January 5, 2005 at the referenced location. Groundwater monitoring well locations are shown on **Figure 1**. The gauging and sampling activities were performed on behalf of the Rhode Island Department of Administration. Following is a report of findings.

Depth to groundwater was gauged in well MW-3 on December 8, 2004, with an interface probe. Separate phase petroleum was detected at a measured thickness of 1.08 feet. The separate phase petroleum was sampled, submitted to a Rhode Island certified laboratory, and analyzed for Fingerprint analysis by EPA Method D3328 and for PCBs by EPA Method 8015B. The MW-3 petroleum sample chromatogram "most closely resembles a combination of gasoline range distillate and a lube stock distillate (motor oil, etc.)" according to the certificate of analysis (**Appendix 1**). PCBs were reported to be present in the MW-3 petroleum sample; Aroclor-1016 and Aroclor 1260 at concentrations of 68 and 48 milligrams per kilogram, respectively. A Water Level Measurements sheet is included in **Appendix 2**.

Groundwater was gauged and sampled at monitoring wells MW-1, MW-5, MW-6 and MW-8 on December 30, 2004. Well MW-7 was gauged and sampled six days later on January 5, 2004. A Water Level Measurements sheet is included in **Appendix 2**. A groundwater table elevation contour map is included as **Figure 2**.

No separate phase petroleum was observed in wells MW-1, MW-5, MW-6, MW-7 and MW-8. The groundwater samples from these wells were submitted to a Rhode Island certified laboratory and analyzed for volatile organic compounds (VOCs) by EPA Method 8260, semivolatile organic compounds (SVOCs) by EPA Method 8270 and for PCBs by EPA Method 8082. VOCs and SVOCs were detected in all of the groundwater samples but at concentrations less than the Rhode Island GB Groundwater Objectives. No PCBs were detected in the groundwater samples. Groundwater analytical results are summarized in **Tables 1 and 2.** The groundwater sample certificate of analysis is included in **Appendix 3**.

Lincoln recommends that additional subsurface investigation be performed to define the extent of the separate phase petroleum observed at MW-3.

If you have any questions, please contact the undersigned at 232-3353, extension 133.

Sincerely,

LINCOLN ENVIRONMENTAL, INC.

Stephen C. Gautie
Hydrogeologist

1. INTRODUCTION AND BACKGROUND

On behalf of the Rhode Island Department of Administration, EA Engineering, Science, and Technology, Inc. (EA) is submitting this Site Investigation Report in accordance with the Rhode Island Department of Environmental Management (RIDEM) *Rules and Regulations for the Investigation and Remediation of Hazardous Material Releases* (*Remediation Regulations*), March 1993, as amended August 1996 and February 2004. This report describes the investigation and sampling activities conducted to support the remediation and closure of the Former Truk-Away Landfill (the Site), Warwick Industrial Drive, Warwick, Rhode Island, under the RIDEM Voluntary Landfill Closure Program. The Site location is depicted on Figure 1.

2. SITE DESCRIPTION AND PREVIOUS ENVIRONMENTAL INVESTIGATIONS

The Former Truk-Away Landfill, located at the eastern end of Warwick Industrial Drive, is currently undeveloped, vegetated, and secured with a chain-link fence, although evidence of trespassing was visible during this investigation. Figure 1 is a Site Locus Map depicting the location of the former landfill. The Site is abutted to the west by industrial use, to the north by a runway for T.F. Green Airport, to the north and east by wetlands, including Buckeye Brook, and to the south by a single-family residential development.

The entire property has an area of 52 acres, 34 of which were used for waste disposal. The remaining 16 acres are freshwater wetlands associated with Buckeye Brook. According to the U.S. Environmental Protection Agency, oily wastes were disposed of in the western portion of the landfill, medical wastes in the west and southeast portions, fly ash in the eastern portion, and mercury film packs to the southern portion. Refuse visible at ground level generally includes paper and glass, with larger debris such as metal pieces in the northwestern portion of the Site.

The depth to groundwater at the Site ranges from 3 to 17 ft below ground surface (bgs), and the flow direction is to the east. There are no public wells within 4 radial miles of the Site. According to the City of Warwick Water Department, the nearest private drinking water wells are located greater than 2 miles from the Site. Based on the locations of the nearest drinking water supply wells, no impacts to drinking water sources are known or suspected. In previous investigations, groundwater was found to flow radially from the center of the landfill towards wetlands to the north, east, and south.

The Site began operation as a privately-owned and operated landfill in 1970, under the name Warwick Sanitary Landfill. The company changed its name to Truk-Away of Rhode Island, Inc. in 1976. Truk-Away was closed in 1977 by the Rhode Island Department of Transportation (RIDOT). RIDOT assumed ownership of the property in 1977.

In 1982, Ecology and Environment, Inc. conducted a Preliminary Assessment (PA) of the Landfill property. During the PA, vapor sampling, which detected tetrachloroethylene and toluene, was conducted along leachate seeps. In response to public complaints, RIDEM collected samples from a pond bordering the Landfill. Analytical results indicated the presence of polychlorinated biphenyls (PCBs) in surface water and three volatile organic compounds (VOCs) in sediment. In 1990, there were reports that the Site continued to be used for illegal dumping of solid waste; there was anecdotal evidence that this dumping may have continued through 1992. The former Truk-Away Landfill is listed on the Comprehensive Environmental Response, Compensation, and Liability, Information System (CERCLIS) under the ID number RID987493822 and has not been officially closed.

In 1993, Camp, Dresser, and McKee, Inc. (CDM) conducted sediment and soil sampling, which indicated the presence of VOCs, semivolatile organic compounds (SVOCs), PCBs, and metals. In 2000, CDM further investigated the Site to assess its suitability for redevelopment. In October 2000, 22 test pits were advanced around the perimeter of the Site to determine the lateral extent of landfill material. Material including plastic, glass, wood, rubber, cloth, and brick were

noted in these test pits. It was found that landfill material extends beyond the southern and western Site boundaries. Waste material was noted at a maximum thickness of 40 ft during the follow-up interior Site soil boring installation at MW-3, located in the central portion of the Site. No waste was observed within MW-7 located adjacent to the wetland area in the northwest portion of the Site. Soils below the waste layer (70-72 ft bgs) at MW-3 exhibited no SVOCs, PCBs, or pesticides above the laboratory detection limits, and exhibited trace levels VOCs, primarily those related to petroleum constituents. All compounds were present below the applicable RIDEM GB Leachability Criteria. Arsenic was detected at MW-7 (10-12 ft bgs), located in the northwestern corner of the Site, and MW-1 (20-22 ft bgs), located in the western portion of the Site near Warwick Industrial Drive, above the RIDEM Industrial/Commercial Direct Exposure Criteria.

Six groundwater monitoring wells were installed during the November 2001 soil boring advancement. During the subsequent sampling activities, approximately 2 ft of light non-aqueous phase liquid (LNAPL) was observed on MW-3, and less than 0.25 in. of LNAPL was observed on MW-5, located on the eastern extent of the Site. A strong landfill gas odor was reported at MW-1. Toluene and ethylbenzene, all petroleum-related VOCs, were detected above the RIDEM GB Groundwater Objectives at MW-3, and ethylbenzene was also detected above the RIDEM GB Groundwater Objectives at MW-8, located on the northern edge of the Site to the north of MW-3. No PCBs, SVOCs, pesticides, or other VOCs were detected above the RIDEM standards.

Also, as part of the CDM investigation in 2000, soil vapor probes were installed around the landfill perimeter and on the top of the landfill. Landfill gas, particularly elevated levels of methane, were noted in 8 out of the 16 probe locations.

In a letter to RIDEM dated 17 February 2005, Lincoln Environmental, Inc. described a groundwater sampling event conducted in December 2004. During this event, 1.08 ft of LNAPL was observed on MW-3, and no evidence of the previously observed LNAPL was measured on MW-5. Groundwater samples were collected from each of the six existing monitoring wells for analysis of PCBs, VOCs, and SVOCs. No PCBs were detected within groundwater, and concentrations of VOCs and SVOCs were below the applicable RIDEM criteria. In addition to groundwater samples, a sample of the LNAPL from MW-3 was also collected. It was shown through petroleum fingerprinting to be a mix of gasoline and motor oil. Results also indicated the presence of two PCB Archlors (1016 and 1260) at 68 and 48 parts per million (ppm), respectively.

3. FIELD ACTIVITIES

In order to determine the current status of the landfill, as well as estimate the required steps to bring the Site into compliance with RIDEM standards, EA conducted a site investigation at the former landfill in accordance with Section 7.0 of the RIDEM *Rules and Regulations for the Investigation and Remediation of Hazardous Material Releases* (*Remediation Regulations*), March 1993, as amended August 1996 and February 2004 and two approved Site Investigation Work Plan dated 5 February and 8 March 2008. EA also conducted a soil gas survey to determine whether the landfill is causing any air issues. Investigation locations were chosen to determine the extent of free-product petroleum-based material in the vicinity of MW-3.

3.1 SOIL BORING INSTALLATION

On 4 March 2008, five soil borings were installed in the vicinity of MW-3 using a Geoprobe. During drilling activities, groundwater was generally encountered within 3 ft of ground surface, presumably due to slower infiltration rates through debris following snow melting. Therefore, the recovery of soils and waste from increasing depths was difficult because wet soil/debris does not allow for a hole to be kept open following soil removal. Boring logs are included as Appendix A.

Several attempts were made to advance a soil boring adjacent to MW-3 to determine a potential source of the contamination previously noted, and to note the extent of petroleum within the unsaturated zone. Refusal was encountered at approximately 14 to 15 ft bgs during each of four attempts. Evidence of minor petroleum impacts, such as a slight sheen on groundwater within the examined soils and a slight odor, were noted at varying depths within the observed waste material (i.e., mixed wood, plastic, glass, metal, and paper). No elevated headspace readings were noted. During the fifth attempt to install a boring to the depth of the screen at MW-3 (i.e., 24 ft bgs), the Geoprobe was able to advance beyond the previous refusal. At a level of approximately 23 to 24 ft bgs, during the removal of the drilling casing, explosive conditions in the form of landfill gas release was encountered. Drilling was suspended due to safety concerns by EA and the Geoprobe contractor. However, a monitoring well, MW-EA-01, was installed in this location following stabilization. This monitoring well was screened only 5 ft (i.e., from 17-23 ft bgs), due to the inability to remove the rest of the steel casing. MW-EA-01 was constructed with 15 ft of solid polyvinyl chloride (PVC) riser and ten feet of 0.010 screened PVC at the bottom of the well. The annulus of bore hole was filled with No. 1 filter sand to 2 ft above the screened interval and a bentonite seal was placed above the sand pack. Native soils and fill were used to fill the remainder of the annulus.

On 4 March 2008, four additional soil borings were installed in the general eastern direction relative to MW-3 in an attempt to delineate any free-product petroleum. Waste material was observed in all borings within 2 to 5 ft of the ground surface. This material consisted of a variety of metal, paper, wood, and plastic and also included discrete layers of apparent ash material. No evidence of significant petroleum contamination was noted during drilling and no headspace readings above 0.0 ppm were noted.

On 29 May 2008, EA installed a second groundwater monitoring well (MW-EA-02) downgradient of the previously encountered pressurized landfill gas at MW-EA-01. MW-EA-02 was installed to a total depth of 25 ft bgs, and was constructed with 15 ft of solid PVC riser and ten feet of 0.010 screened PVC at the bottom of the well. The annulus of bore hole was filled with No. 1 filter sand to two feet above the screened interval and a bentonite seal was placed above the sand pack. Native soils and fill were used to fill the remainder of the annulus.

3.2 SOIL GAS SURVEY

EA retained a Geoprobe contractor to install 1-in. soil vapor sampling points throughout the Site. On 29 May 2008, a total of nine soil vapor points were installed in the vicinity of the previously encountered pocket of landfill gas. Approximate locations are depicted on Figure 2. At each location, the 1-in. PVC point was installed to a depth of 6 ft. bgs. The bottom 1 ft of this PVC was screened with 0.010-in. slotted screen, and the remainder of the point was solid PVC riser. Polyethylene tubing was installed through a drilled hole in the top of the well to allow for subsequent monitoring with field equipment. Following the installation of each PVC point, the annular space was filled with No. 1 sand, a bentonite seal was installed above the screened portion, and the point was capped. Prior to recording soil gas concentrations, each point was purged for at least 2 minutes to remove residual vapor from previous points or ambient air in the PVC. Concentrations of VOCs were measured using a photo-ionization detector (PID), and concentrations of oxygen, methane, carbon dioxide, and hydrogen sulfide were measured using a portable landfill gas meter. Results are summarized in Table 1 below.

TABLE 1 SOIL GAS SCREENING RESULTS – 29 MAY 2008

SVE Point ID	% Methane (CH_4)	% Carbon Dioxide (CO_2)	% Oxygen (O_2)	VOCs (ppm)
SV-01	71.1	36.0	0.2	1.7
SV-02	71.3	35.2	0.5	2.0
SV-03	41.7	16.6	8.2	0.45
SV-04	34.8	14.7	10.5	1.3
SV-05	62.3	30.6	3.1	2.5
SV-06	41.2	8.2	18.6	1.5
SV-07	0.4	0.1	21.7	3.7
SV-08	59.2	28.7	04.6	1.7
SV-09	37.9	16.4	9.9	1.5
Note: The Lower Explosive Limit (LEL) for methane is 5% methane.				

Results of this soil gas survey indicate that the levels of soil gas present at the former landfill exceed the Lower Explosive Limit (LEL) for methane at all but one location in the vicinity of MW-3.

3.3 GROUNDWATER MONITORING WELL INSTALLATION AND SAMPLING

On 4 June 2008, EA performed one round of groundwater sampling at all Site wells. The wells were sampled using a peristaltic pump and dedicated polyethylene tubing in accordance with the Environmental Protection Agency's (EPA) Low-Flow Procedure. Data collected from each well

immediately prior to sampling are summarized in Table 2 below, and the complete groundwater monitoring data is included as Appendix B.

TABLE 2 GROUNDWATER MONITORING DATA – 5 JUNE 2008

	MW-EA1	MW-EA2	MW-1	MW-5	MW-6	MW-7	MW-8
Time	9:45	9:32	12:15	14:55	14:37	15:50	12:13

Oxidation/Reduction Potential (mV)	-101.9	-114.6	-92.1	-111.9	-162.2	-138.9	-99.7
Dissolved Oxygen (mg/L)	0.94	0.32	16.42	4.99	0.19	0.18	0.25
Turbidity (NTU)	3.76	7.6	8.67	0.49	3.8	4.47	9.0
Volume Purged (gallons)	2.5	1.4	1.25	1.25	1.5	1.0	1.2

Note: mS/cm = Milisiemens per centimeter.
mV = Milivolts.
NTU = Normal Turbidity Units.

As specified in the Site Investigation Work Plan, prepared by EA and approved by the RIDEM, all samples were placed in a cooler with ice and transported to a Rhode Island Certified Laboratory for analysis of VOCs via EPA method 8260. Analytical results indicate compliance with all RIDEM GB Groundwater Objectives. Concentrations of detected analytes are summarized in Table 3 below. Certificates of Analysis are included as Appendix C.

-- = No RIDEM GB Groundwater Objective established for this analyte.
RIDEM GB-LC: GB Leachability Criteria as defined in Section 8.02 of RIDEM Remediation Regulations.
Bold indicates an exceedances of the applicable RIDEM standards.

In addition to the groundwater sampling, one sample of free product was collected from MW-3 through the use of a polyethylene bailer. This sample was submitted for analysis of VOC, pesticides via EPA method 8081, PCB via EPA method 8082, and SVOCs via EPA method 8270. Concentrations of detected analytes are summarized in Table 4 below. Certificates of Analysis are included as Appendix D.

TABLE 4 FREE PRODUCT ANALYTICAL RESULTS – 5 JUNE 2008

Analyte Detected	MW-3 (Free Product)
Volatile Organic Compounds	
1,1,1-Trichloroethane	38.5
1,1-Dichloroethane	20.0
1,2,4-Trimethylbenzene	4520
1,3,5-Trimethylbenzene	1420

Semi-Volatile Organic Compounds	
bis(2-Ethylhexyl)phthalate	2530
Naphthalene	778

Note: All results reported in mg/L.
ND = Not detected above the laboratory Method Detection Limit.

4. REMEDIAL ALTERNATIVES

Based upon the data collected during this investigation and those previously conducted, it has been determined that remediation is required to bring the former landfill into compliance with the applicable regulations. There are two primary areas of concern at the Site: LNAPL within MW-3, and issues from waste and soil contamination. Three remedial alternatives are presented below for each area of concern, with a recommendation made for the one that is considered to be most practical.

4.1 LIGHT NON-AQUEOUS PHASE LIQUID

4.1.1 LNAPL Remedial Alternative No. 1 – No Action

This remedial alternative involves allowing the LNAPL noted on MW-3 to naturally attenuate using no active remediation. However, as LNAPL exceeds the Upper Concentration Limit for petroleum, this alternative would not address this contamination in a proactive manner. Data indicates that the LNAPL may be bound by buried debris and therefore may not be affected by natural attenuation processes. Therefore, this remedial alternative is not recommended.

4.1.2 LNAPL Remedial Alternative No. 2 – Active Product Recovery System

This remedial alternative involves the construction of a product recovery system to remove the LNAPL from MW-3 and isolate it for off-site disposal. The system would include a floating skimmer to collect the LNAPL from the well. The LNAPL would then be pumped to an above ground storage vessel. However, in a remote area like that of the Site, it would be difficult to monitor the system for potential overflows of malfunctions. In addition, based on the nearby residents and evidence of trespassing on the Site despite fencing, any constructed system may be subject to vandalizing or may serve as a potential source for injury.

4.1.3 LNAPL Remedial Alternative No. 3 – Combination Active/Passive Recovery System

In this preferred remedial alternative, LNAPL would be addressed using a combination of regular hand-bailing and containment of the product with passive recovery features remaining in MW-3 between bailing events. All LNAPL collected will be stored temporarily in drums pending off-site disposal. Given the suspension of landfilling activities and, therefore, no new source of contamination, it is expected that the volume of LNAPL will decrease over time. As MW-3 is located in the central and topographically highest portion of the Site, and no evidence of LNAPL was noted in downgradient wells during the recent sampling event, this remedial alternative is preferred as an effective but low-impact method of addressing the LNAPL at MW-3.

4.2 WASTE AND SOIL CONTAMINATION

4.2.1 Waste and Soil Contamination Remedial Alternative No. 1 – No Action

In this remedial alternative, Site conditions would not be changed. However, this alternative is not recommended due to protruding debris along the perimeter of the former landfill, particularly in relation to the wetland areas, and insufficient cap material present at this time.

4.2.2 Waste and Soil Contamination Remedial Alternative No. 2 – Removal and Off-Site Disposal

One alternative which prevents future direct exposure issues or migration risks from remaining waste and impacted soil at the Site is to remove the solid waste associated with former landfill operations and transport the waste to a licensed disposal facility. The source of this contamination would be removed from the property, thereby eliminating the risk of impacts residents, wetlands, or future developments. However, this remedial alternative is not recommended. First, due to the size of the Site, this is an impractical solution. In addition, opening the landfill during excavation could create exposure and migration issues for nearby residents and the adjacent runways. Restoring the property to pre-waste disposal condition will be costly and time-consuming and will ultimately not positively impact environmental quality or address the needs of the neighborhood.

4.2.3 Waste and Soil Contamination Remedial Alternative No. 3 – Engineered Cap and Environmental Land Usage Restriction

The third and preferred remedial alternative involves the construction of an engineered cap at the Site. Prior to cap construction, surficial debris removal will be conducted, particularly along areas adjacent to the wetland areas around the perimeter of the Site, and at the top of the former landfill, to address the exposed miscellaneous waste. Clearing, grubbing, and rough grading will also be required to establish a suitable base for construction. An engineered cap will then be constructed throughout the Site. This cap will act as a further barrier against human exposure to contaminated soils and fill material. This engineered cap will likely consist of 2 ft of certified clean fill material or equivalent. The top of the cap will consist of topsoil to support vegetation. Vegetation with an acceptable root penetration will improve the value of the former landfill as a habitat and prevent soil erosion in the future. Regular inspections of this engineered cap will be required to ensure its effectiveness.

An Environmental Land Usage Restriction (ELUR) documenting maintenance, and annual inspections of the engineered cap will be recorded in the land evidence records for the property following completion of the remedial activities. The ELUR will include requirements for annual cap inspections and reports to RIDEM, as well as a soil management plan to prescribe measures to be taken in the event of future excavation activities at the Site.

EA recommends the implementation of this remedial alternative to bring the former Truk-Away Landfill into compliance with the RIDEM Remediation Regulations. This remedial alternative will isolate the exposed waste material from direct exposure, and prevent potential migration onto residential properties or into Site wetlands in the future. Upon RIDEM concurrence with this remedial alternative, a Remedial Action Work Plan containing a detailed design to complete the final closure of the former Truk-Away Landfill will be submitted.

5. CERTIFICATIONS

The undersigned certify that this Site Investigation Report is a complete and accurate representation of the activities that occurred at the Site and contains all known facts surrounding the Site to the best of their knowledge.

RE: Truck Away
ESS Laboratory Work Order Number: 0806089

This signed Certificate of Analysis is our approved release of your analytical results. These results are only representative of sample aliquots received at the laboratory. ESS Laboratory expects its clients to follow all regulatory sampling guidelines. Beginning with this Project Narrative, the entire report has been paginated. The ESS Laboratory Certifications sheet is the final report page. This report should not be copied except in full without the approval of the laboratory. Samples will be disposed of thirty days after the final report has been mailed. If you have any questions or concerns, please feel free to call our Customer Service Department.

Laurel Stoddard
Laboratory Director

Date: June 13, 2008

Analytical Summary
The project as described above has been analyzed in accordance with the ESS Quality Assurance Plan. This plan utilizes the following methodologies: US EPA SW-846, US EPA Methods for Chemical Analysis of Water and Wastes per 40 CFR Part 136, APHA Standard Methods for the Examination of Water and Wastewater, American Society for Testing and Materials (ASTM), and other recognized methodologies. The analyses with these noted observations are in conformance to the Quality Assurance Plan. In chromatographic analysis, manual integration may be used instead of automated integration because it produces more accurate results. All ICP Metals were analyzed using the established linear dynamic range to determine acceptable analytical results.

ESS Laboratory certifies that the test results meet the requirements of NELAC, except where noted within this project narrative.

Sample Receipt
The following sample(s) were received on June 06, 2008 for the analyses specified on the enclosed Chain of Custody Record.

Laboratory ID	Matrix	Client SampleID
0806089-01	Ground Water	MWEA-2
0806089-02	Ground Water	MWEA-1
0806089-03	Oil	MW-3
0806089-04	Ground Water	MW-8
0806089-05	Ground Water	MW-1
0806089-06	Ground Water	MW-6
0806089-07	Ground Water	MW-5
0806089-08	Ground Water	MW-7
0806089-09	Aqueous	Trip Blank

Client Project ID: Truck Away

ESS Laboratory Work Order: 0806089

PROJECT NARRATIVE

5035/8260B Volatile Organic Compounds / Methanol

0806089-03	**Surrogate recovery(ies) diluted below the MRL.**
BF81003-BSD1	**Blank Spike recovery is above upper control limit.** 2-Butanone, Acetone, Vinyl Chloride

8081A Organochlorine Pesticides

0806089-03	**Percent difference between primary and confirmation results exceeds 40%.** 4,4´-DDD, alpha-Chlordane, beta-BHC, delta-BHC, gamma-Chlordane, Heptachlor Epoxide, Hexachlorobenzene
0806089-03	**Surrogate recovery(ies) diluted below the MRL.**
BF81021-DUP1	**Surrogate recovery(ies) diluted below the MRL.**
BF81021-MS1	**Matrix Spike is diluted below the MRL.**
BF81021-MS1	**Surrogate recovery(ies) diluted below the MRL.**

8082 Polychlorinated Biphenyls (PCB)

0806089-03	**Percent difference between primary and confirmation results exceeds 40%.** Aroclor 1260
0806089-03	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BF80629-DUP1	**Percent difference between primary and confirmation results exceeds 40%.** Aroclor 1260
BF80629-DUP1	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BF80629-MS1	**Matrix Spike recovery is above upper control limit.** Aroclor 1016
BF80629-MS1	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**

8260B Volatile Organic Compounds

0806089-02	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
0806089-06	**Reported above the quantitation limit; Estimated value.** 1,4-Dioxane - Screen

8270C Semi-Volatile Organic Compounds

0806089-03	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BF80634-BS1	**Blank Spike recovery is below lower control limit.** 2,4-Dinitrophenol, Hexachlorocyclopentadiene
BF80634-BSD1	**Blank Spike recovery is below lower control limit.** 2,4-Dinitrophenol, Hexachlorocyclopentadiene
BF80634-DUP1	**Relative percent difference for duplicate is outside of criteria.** 2-Methylnaphthalene
BF80634-DUP1	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BF80634-MS1	**Majority of matrix spike compounds are outside of criteria due to matrix interferences.**
BF80634-MS1	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BRD0277-CCV1	**Continuing Calibration recovery is below lower control limit.** Hexachlorocyclopentadiene
BRF0081-CCV1	**Continuing Calibration recovery is below lower control limit.** 2-Methylnaphthalene

RE: Truck Away
ESS Laboratory Work Order Number: 0806089

This signed Certificate of Analysis is our approved release of your analytical results. These results are only representative of sample aliquots received at the laboratory. ESS Laboratory expects its clients to follow all regulatory sampling guidelines. Beginning with this Project Narrative, the entire report has been paginated. The ESS Laboratory Certifications sheet is the final report page. This report should not be copied except in full without the approval of the laboratory. Samples will be disposed of thirty days after the final report has been mailed. If you have any questions or concerns, please feel free to call our Customer Service Department.

Laurel Stoddard
Laboratory Director

Date: June 13, 2008

Analytical Summary
The project as described above has been analyzed in accordance with the ESS Quality Assurance Plan. This plan utilizes the following methodologies: US EPA SW-846, US EPA Methods for Chemical Analysis of Water and Wastes per 40 CFR Part 136, APHA Standard Methods for the Examination of Water and Wastewater, American Society for Testing and Materials (ASTM), and other recognized methodologies. The analyses with these noted observations are in conformance to the Quality Assurance Plan. In chromatographic analysis, manual integration may be used instead of automated integration because it produces more accurate results. All ICP Metals were analyzed using the established linear dynamic range to determine acceptable analytical results.

ESS Laboratory certifies that the test results meet the requirements of NELAC, except where noted within this project narrative.

Sample Receipt
The following sample(s) were received on June 06, 2008 for the analyses specified on the enclosed Chain of Custody Record.

Laboratory ID	Matrix	Client SampleID
0806089-01	Ground Water	MWEA-2
0806089-02	Ground Water	MWEA-1
0806089-03	Oil	MW-3
0806089-04	Ground Water	MW-8
0806089-05	Ground Water	MW-1
0806089-06	Ground Water	MW-6
0806089-07	Ground Water	MW-5
0806089-08	Ground Water	MW-7
0806089-09	Aqueous	Trip Blank

ESS Laboratory Work Order: 0806089

PROJECT NARRATIVE

5035/8260B Volatile Organic Compounds / Methanol

0806089-03	**Surrogate recovery(ies) diluted below the MRL.**
BF81003-BSD1	**Blank Spike recovery is above upper control limit.** 2-Butanone, Acetone, Vinyl Chloride

8081A Organochlorine Pesticides

0806089-03	**Percent difference between primary and confirmation results exceeds 40%.** 4,4'-DDD, alpha-Chlordane, beta-BHC, delta-BHC, gamma-Chlordane, Heptachlor Epoxide, Hexachlorobenzene
0806089-03	**Surrogate recovery(ies) diluted below the MRL.**
BF81021-DUP1	**Surrogate recovery(ies) diluted below the MRL.**
BF81021-MS1	**Matrix Spike is diluted below the MRL.**
BF81021-MS1	**Surrogate recovery(ies) diluted below the MRL.**

8082 Polychlorinated Biphenyls (PCB)

0806089-03	**Percent difference between primary and confirmation results exceeds 40%.** Aroclor 1260
0806089-03	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BF80629-DUP1	**Percent difference between primary and confirmation results exceeds 40%.** Aroclor 1260
BF80629-DUP1	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BF80629-MS1	**Matrix Spike recovery is above upper control limit.** Aroclor 1016
BF80629-MS1	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**

8260B Volatile Organic Compounds

0806089-02	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
0806089-06	**Reported above the quantitation limit; Estimated value.** 1,4-Dioxane - Screen

8270C Semi-Volatile Organic Compounds

0806089-03	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BF80634-BS1	**Blank Spike recovery is below lower control limit.** 2,4-Dinitrophenol, Hexachlorocyclopentadiene
BF80634-BSD1	**Blank Spike recovery is below lower control limit.** 2,4-Dinitrophenol, Hexachlorocyclopentadiene
BF80634-DUP1	**Relative percent difference for duplicate is outside of criteria.** 2-Methylnaphthalene
BF80634-DUP1	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BF80634-MS1	**Majority of matrix spike compounds are outside of criteria due to matrix interferences.**
BF80634-MS1	**Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).**
BRD0277-CCV1	**Continuing Calibration recovery is below lower control limit.** Hexachlorocyclopentadiene
BRF0081-CCV1	**Continuing Calibration recovery is below lower control limit.** 2-Methylnaphthalene

CERTIFICATE OF ANALYSIS

Client Name: EA Engineering, Science, and Technology
Client Project ID: Truck Away ESS Laboratory Work Order: 0806089

Notes and Definitions

U	Analyte included in the analysis, but not detected
SM	Surrogate recovery(ies) outside of criteria due to matrix (UCM/coelution is present).
SD	Surrogate recovery(ies) diluted below the MRL.
P	Percent difference between primary and confirmation results exceeds 40%.
MM	Majority of matrix spike compounds are outside of criteria due to matrix interferences.
MD	Matrix Spike is diluted below the MRL.
M+	Matrix Spike recovery is above upper control limit.
E	Reported above the quantitation limit; Estimated value.
D+	Relative percent difference for duplicate is outside of criteria.
D	Diluted.
C-	Continuing Calibration recovery is below lower control limit.
B+	Blank Spike recovery is above upper control limit.
B-	Blank Spike recovery is below lower control limit.
ND	Analyte NOT DETECTED above the detection limit
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference
MDL	Method Detection Limit
MRL	Method Reporting Limit
I/V	Initial Volume
F/V	Final Volume
§	Subcontracted analysis; see attached report
1	Range result excludes concentrations of surrogates and/or internal standards eluting in that range.
2	Range result excludes concentrations of target analytes eluting in that range.
3	Range result excludes the concentration of the C9-C10 aromatic range.
Avg	Results reported as a mathematical average.

SITE INVESTIGATION PLAN
FIGURE 2

On 29 May 2008, EA installed a second groundwater monitoring well (MW-EA-02) downgradient of the previously encountered pressurized landfill gas at MW-EA-01. MW-EA-02 was installed to a total depth of 25 ft bgs, and was constructed with 15 ft of solid PVC riser and ten feet of 0.010 screened PVC at the bottom of the well. The annulus of bore hole was filled with No. 1 filter sand to two feet above the screened interval and a bentonite seal was placed above the sand pack. Native soils and fill were used to fill the remainder of the annulus.

3.2 SOIL GAS SURVEY

EA retained a Geoprobe contractor to install 1-in. soil vapor sampling points throughout the Site. On 29 May 2008, a total of nine soil vapor points were installed in the vicinity of the previously encountered pocket of landfill gas. Approximate locations are depicted on Figure 2. At each location, the 1-in. PVC point was installed to a depth of 6 ft. bgs. The bottom 1 ft of this PVC was screened with 0.010-in. slotted screen, and the remainder of the point was solid PVC riser. Polyethylene tubing was installed through a drilled hole in the top of the well to allow for subsequent monitoring with field equipment. Following the installation of each PVC point, the annular space was filled with No. 1 sand, a bentonite seal was installed above the screened portion, and the point was capped. Prior to recording soil gas concentrations, each point was purged for at least 2 minutes to remove residual vapor from previous points or ambient air in the PVC. Concentrations of VOCs were measured using a photo-ionization detector (PID), and concentrations of oxygen, methane, carbon dioxide, and hydrogen sulfide were measured using a portable landfill gas meter. Results are summarized in Table 1 below.

TABLE 1 SOIL GAS SCREENING RESULTS – 29 MAY 2008

SVE Point ID	% Methane (CH_4)	% Carbon Dioxide (CO_2)	% Oxygen (O_2)	VOCs (ppm)
SV-01	71.1	36.0	0.2	1.7
SV-02	71.3	35.2	0.5	2.0
SV-03	41.7	16.6	8.2	0.45
SV-04	34.8	14.7	10.5	1.3
SV-05	62.3	30.6	3.1	2.5
SV-06	41.2	8.2	18.6	1.5
SV-07	0.4	0.1	21.7	3.7
SV-08	59.2	28.7	04.6	1.7
SV-09	37.9	16.4	9.9	1.5
Note: The Lower Explosive Limit (LEL) for methane is 5% methane.				

Results of this soil gas survey indicate that the levels of soil gas present at the former landfill exceed the Lower Explosive Limit (LEL) for methane at all but one location in the vicinity of MW-3.

3.3 GROUNDWATER MONITORING WELL INSTALLATION AND SAMPLING

On 4 June 2008, EA performed one round of groundwater sampling at all Site wells. The wells were sampled using a peristaltic pump and dedicated polyethylene tubing in accordance with the Environmental Protection Agency's (EPA) Low-Flow Procedure. Data collected from each well

immediately prior to sampling are summarized in Table 2 below, and the complete groundwater monitoring data is included as Appendix B.

TABLE 2 GROUNDWATER MONITORING DATA – 5 JUNE 2008

Note: mS/cm = Milisiemens per centimeter.
mV = Milivolts.
NTU = Normal Turbidity Units.

As specified in the Site Investigation Work Plan, prepared by EA and approved by the RIDEM, all samples were placed in a cooler with ice and transported to a Rhode Island Certified Laboratory for analysis of VOCs via EPA method 8260. Analytical results indicate compliance with all RIDEM GB Groundwater Objectives. Concentrations of detected analytes are summarized in Table 3 below. Certificates of Analysis are included as Appendix C.

RIDEM GB-LC: GB Leachability Criteria as defined in Section 8.02 of RIDEM Remediation Regulations.
Bold indicates an exceedances of the applicable RIDEM standards.

In addition to the groundwater sampling, one sample of free product was collected from MW-3 through the use of a polyethylene bailer. This sample was submitted for analysis of VOC, pesticides via EPA method 8081, PCB via EPA method 8082, and SVOCs via EPA method 8270. Concentrations of detected analytes are summarized in Table 4 below. Certificates of Analysis are included as Appendix D.

TABLE 4 FREE PRODUCT ANALYTICAL RESULTS – 5 JUNE 2008

NS = Not Sampled; ND = Non Detect; R=Rejected because data did not meet data quality objectives

OF08=Outfall from airport that drains passenger tarmac area TA01=Truk-Away station

AP01=Downstream from confluence of the combined flows from OF08 and TA01. Only sampled during DW2 (9/10/2008).

TOC was added only for the 2nd dry survey when biological sampling was conducted.

RIDEM Policy: For averages, a ND is treated as a NS (Not Sampled). If below Reporting Limit, a value of 0 is used for averages.

If the DOH lab had a value for a sample that was below the Reporting limit (RL) but above the detection limit (DL) the QAPP required that the lab report that value to RIDEM. The RIDEM staff would then evaluate the value and list it as below the RL (<0.XX) as you see above. However, if the constistuent was not present at all in the sample, a Non Detect (ND) was reported.

Sampling Dates: Run 1-02/01/11; Run 2-02/03/11; Run 3- 02/06/11; Run 4- 02/08/11; ND = Non-Detect; R=Rejected because data did not meet data quality objectives.

TA01=Truk-Away station OF08=Outfall from airport that drains passenger tarmac area

*The Run 1 sample collected for this survey was prior to storm commencement and is considered under dry weather conditions (2/1/2011).

RIDEM Policy: For averages, a ND is treated as a NS (Not Sampled). If below Reporting Limit, a value of 0 is used for averages.
If the DOH lab had a value for a sample that was below the Reporting limit (RL) but above the detection limit (DL) the QAPP required that the lab report that value to RIDEM. The RIDEM staff would then evaluate the value and list it as below the RL (<0.XX) as you see above. However, if the constistuent was not present at all in the sample, a Non Detect (ND) was reported.

								End of exploration at 10 feet.	3 4		10			

REMARKS

1 - The headspace of soil samples was screened for Total Volatile Organic Compounds (TVOCs) using a MiniRae model 3000 Photoionization Detector (PID) equipped with a 10.6 cV lamp. ND indicates non-detected reading below the instrument's detection limit of approximately 0.1 ppm.
2 - Groundwater observed at ±3ft bgs.
3 - End of exploration at ±10ft bgs.
4 - Observation well (2"PVC) installed at 10ft bgs; screened from 10-0ft bgs.

See Log Key for exploration of sample description and identification procedures. Stratification lines represent approximate boundaries between soil and bedrock types. Actual transitions may be gradual. Water level readings have been made at the times and under the conditions stated. Fluctuations of groundwater may occur due to other factors than those present at the times the measurements were made.

REMARKS

1 - Driller drove 4" casing to 30ft bgs and installed an observation well (2" PVC) at 30 ft bgs; screened from 30-25ft bgs.
2 - Landfill gas odor present.

See Log Key for exploration of sample description and identification procedures. Stratification lines represent approximate boundaries between soil and bedrock types. Actual transitions may be gradual. Water level readings have been made at the times and under the conditions stated. Fluctuations of groundwater may occur due to other factors than those present at the times the measurements were made.

Exploration No.: MW-106D

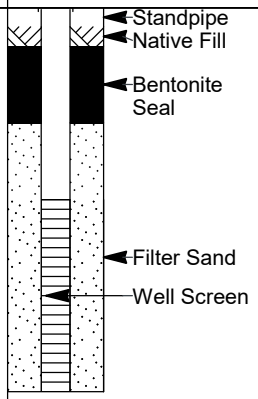
10								End of exploration at 10 feet.	2 3				

Equipment Installed



REMARKS

1 - Shoveled 1.5 ft bgs to evaluate presence of debris, no debris present.
2 - End of exploration at ±10 ft bgs.
3 - Soil gas probe (1/2" PVC) installed at ± 10 ft bgs; screened at ± 10-5 ft bgs.

See Log Key for exploration of sample description and identification procedures. Stratification lines represent approximate boundaries between soil and bedrock types. Actual transitions may be gradual. Water level readings have been made at the times and under the conditions stated. Fluctuations of groundwater may occur due to other factors than those present at the times the measurements were made.

WATER LEVEL OBSERVATIONS

Measurement Date/Time: 1/8/2020 14:28

Point of Measurement: PVC Riser [X] Steel Casing [ ] Ground [ ]

Total Well Depth (feet):	12.45	Standing Water in Well (feet):	7.25
Depth to LNAPL (feet):	--	Well Diameter (in.)	2
Depth to Water (feet):	5.20	Sample Depth (feet BGS):	5
Depth to DNAPL (feet):	--	Standpipe: TPVC to Ground Surface (feet)	--
Well Screened Interval (feet BGS):	0 to 10	Roadbox: TPVC to Ground Surface (feet)	--

Well Condition: **Protective Casing-** [ ] Poor [X] Good **Lock-** [ ] Yes [X] No **Expansion Cap-** [X] Yes [ ] No **Well ID-** [ ] Yes [X] No **Concrete Collar-** [X] Yes [ ] No **Well-** [ ] Poor [X] Good

EQUIPMENT

Sample Method: [ ] Bail [X] Pump / [X] Low Flow

Pump Type: Geotech GeoPump Model Ii No. Rental
Flow-Thru Cell Vol (mL): 500

Meter Type: Ysi Pro Dss No. Rental

INSTRUMENT MEASUREMENTS:

Start time: 8:20 **Stop time:** 9:59

		1	2	3	4	5	6	7	8
Time: _____ (start)	Depth to Water (ft) (drawdown <0.3 or stable)	ORP (mvolts) (± 10)	pH (s.u.) (± 0.1)	Spec. Cond. (mS/cm) (±3%)	DO (mg/L) (±10% or 3 rdgs <0.5)	Temperature (ºC) (±3%)	Turbidity (ntu) (±10% or <5ntu)	Flow (ml/min) (<500 ml/min)	Notes
9:12	5.30	-20.3	6.40	561	2.47	7.3	60.11	<500	
9:15	5.31	-26.9	6.39	567	0.68	7.3	65.60	<500

Flow-Thru Cell Vol (mL): 500

Meter Type: Ysi Pro Dss No. Rental

INSTRUMENT MEASUREMENTS:

Start time: 13:03 **Stop time:** 15:07

		1	2	3	4	5	6	7	8
Time: _____ (start)	Depth to Water (ft) (drawdown <0.3 or stable)	ORP (mvolts) (± 10)	pH (s.u.) (± 0.1)	Spec. Cond. (mS/cm) (±3%)	DO (mg/L) (±10% or 3 rdgs <0.5)	Temperature (ºC) (±3%)	Turbidity (ntu) (±10% or <5ntu)	Flow (ml/min) (<500 ml/min)	Notes
14:50	14.75	-471.9	7.06	747	0.41	9.3	310.3	<500	
15:00	17.35	-464.5	7.07	757	0.39	9.4	244.6	<500	
15:03	17.40	-456.1	7.07	756	0.40	9.4	240.12	<500	
15:07	17.45	-454.3	7.07	757	0.39	9.4	237.37	<500	

SAMPLE TESTING INFORMATION:

SAMPLE TIME: 15:07

Analysis	Method	No. Bottles	Bottle Type	Volume	Preservation	Handling
VOC	EPA Method 8260	3	VOA	40 mL	HCl	Ice
SVOC	EPA Method 8270	2	AG	1 L	NP	Ice
TPH	EPA Method 8100	1	AG	1L	NP	Ice
Pesticides	EPA Method 8081	1	AG	1L	NP	Ice
PCBs	EPA Method 8082	1	AG	1L	NP	Ice
15 Solid Waste Metals/Mercury	EPA Methods 6010/7470	1	Poly	250mL	HNO3	Ice

Sample observations:

Color: Slightly black Odor: None Clarity: Cloudy

Total Purge Volume:

Tubing Volume:

2" WELL = 0.163 GAL /FT = 0.617 LITERS/FT
1" WELL = 0.013 GAL /FT = 0.0492 LITERS/FT
3/8" TUBING - 0.0057 GAL/FT - 0.0217 LITERS/FT
1/4" TUBING - 0.0025 GAL/FT - 0.0096 LITERS/FT

Notes:

NM - Not Measured NP - No Product observed BGS - below ground surface FT - feet in - inches mL - milliliters GAL - gallons mvolts - millivolts s.u. - standard units
mS/cm - microsiemens per centimeter mg/L - milligrams per liter ºC - degrees Celcius ntu - Nephelometric Turbidity Unit mL/min - milliliters per minute

Well very silty when began pumping.

GROUNDWATER SAMPLING DATA SHEET

File No. 34648
Project: Truk-Away Landfill
Location: City: Warwick State: RI
Weather:

Well ID: MW-107
Sample Date: 1/9/2020
Sampler's Name: Rowan Hayes

WATER LEVEL OBSERVATIONS

Measurement Date/Time: 1/9/2020 14:10

Point of Measurement: PVC Riser [X] Steel Casing [ ] Ground [ ]

Total Well Depth (feet):	23.40	Standing Water in Well (feet):	--
Depth to LNAPL (feet):	--	Well Diameter (in.)	2
Depth to Water (feet):	--	Sample Depth (feet BGS):	5
Depth to DNAPL (feet):	--	Standpipe: TPVC to Ground Surface (feet)	--
Well Screened Interval (feet BGS):	0 to 10	Roadbox: TPVC to Ground Surface (feet)	--

Well Condition: **Protective Casing-** [X] Poor [ ] Good **Lock-** [ ] Yes [X] No **Expansion Cap-** [X] Yes [ ] No **Well ID-** [ ] Yes [X] No **Concrete Collar-** [ ] Yes [X] No **Well-** [X] Poor [ ] Good

EQUIPMENT

Sample Method: [ ] Bail [ ] Pump / [ ] Low Flow

Pump Type: No.

Meter Type: No.
