In 2001, The Division of Fish and Wildlife implemented a voluntary sighting log survey for the state’s archery deer hunters. The survey is modeled on similar surveys that have been used successfully for a number of years in other states such as New York and Virginia. The objective of the sighting log survey is to collect reliable information on a variety of wildlife species to help monitor the relative abundance of these species over time.

There are rarely enough personnel and resources available to wildlife managers to conduct population monitoring of more than a few wildlife species and particularly those that do not have to be tagged by the Division of Fish and Wildlife. Harvest data is often relied upon to estimate changes in wildlife populations, yet many variables often make harvest information alone a poor index of population trends. The number of unsolicited sighting reports, nuisance complaints, and road-kills can be related to wildlife population levels and provide useful information. The sighting log will provide an additional source of information, which when combined with other available data will improve our ability to detect changes in population levels for furbearers and other wildlife species. Another use of the survey is to gain a better understanding of distribution of species for which there may be little or no information.

Archery hunters have been the focus of sighting log surveys primarily because most archers still hunt from a stand, allowing them an opportunity to accurately identify any animals they observe. Additionally, the length of the archery season is longer than other methods, extending the observation period over several months. Many muzzleloader and shotgun hunters also hunt from a stand and the term “bowhunter sighting log” should not deter them from participating in the survey.

Participants were asked to record the number of hours hunted and the number of sightings of selected wildlife species each time they hunted throughout the archery deer season. In addition to those species listed on the survey card, participants were asked to record other species observed such as chipmunks, hawks, owls and domestic animals such as cats or dogs. Sightings of other hunters or other people observed while hunting should also be recorded. The number of sightings recorded is converted to a sighting rate (number of sightings/100hrs). The sighting rate can be compared from year to year, from area to area, and can be a useful index of population trends for certain species.

The total number of hunts reported remained about the same as last year but the total number of reported observation hours decreased slightly. During the 2008-2009 season twelve hunters logged 1033.5 hours of observation time during 351 individual outings. Those persons who participated continued to do an excellent job of recording their data. Unlike past years where some cards could not be used because of incorrect or incomplete recording of information, we were able to use all the cards that were returned in our analysis.
Observations were recorded in twenty different towns, one more than 2007-2008. Exeter again led all towns with the highest number of hunts, (86), followed by Coventry (39) and North Kingstown (28). November had the highest number of observation hours (483) as well as the most number of hunts (154). Ninety-seven percent of recorded hunts occurred on private land. The number of antlerless deer sighted statewide per 100 hours of observation time increased by 18.5% after four previous years of decline. The number of bucks observed statewide decreased 36.5% from 7.4/100 hrs in 2007/08 to 4.7/100 hrs in 2008/09.

When looking at the tables, it is important to remember that a change from one year of the survey to the next does not necessarily mean a change in the population. Many factors can affect the visibility of wildlife including weather, availability of food, etc. Also the low number of participants, the distribution of participants and low number of observation hours will affect the data. Over time however, with an adequate and consistent number of participants and better distribution throughout the state, we may be able to detect trends in populations of some species.

The Division of Fish and Wildlife wishes to thank those archers and other hunters that participated in the bowhunter sighting log. Survey forms will be available again this year prior to the opening of the mainland archery deer season. Survey forms can be downloaded from the DEM website: [www.dem.ri.gov](http://www.dem.ri.gov) as well as various check stations and Fish and Wildlife offices. A continued effort will be made to increase the number of participants and the statewide distribution of effort and to refine the survey. The usefulness of the survey will depend on adequate participation and distribution of observers. Other potentially useful data that could be incorporated into the survey might include: weather conditions, number of bucks chasing does, doe to fawn ratios, or number of other hunters observed. Any comments or suggestions to make the survey more effective are welcomed. Survey results will be mailed to all participants who returned a survey card and provided a return address. Survey results are also available at Fish and Wildlife offices. If you know of anyone who might like to participate in the survey contact the Division of Fish and Wildlife at the Great Swamp Field Headquarters, West Kingston, RI. Telephone 401-789-0281.
